As a matter of fact it was the first hospital for the insane to be founded in Ireland, and it remained the only one for some 70 years. The institution has always kept abreast of the best knowledge of the treatment of the insane and, like most other institutions of the kind, it has undergone great development in the last 30 years, during which time it has been under the medical superintendence of Dr. R. R. Leeper. In recent years a country branch has be established in a beautiful country house near Luc some half dozen miles from Dublin. The Govern General, in declaring the new wing open, expres his confidence that the hospital would continue preserve the eighteenth century traditions of charita helpfulness and of sympathetic efficiency, and th the governors would always, as now, recogn professional efficiency by removing obstructions to t application of steadily advancing medical knowled

THE MENTALLY DEFICIENT IN IRELAND.

At a meeting of the Dublin Rotary Club last we Mr. John Cooke, who has been for many ye honorary secretary of the Dublin Branch of t National Society for the Prevention of Cruelty Children, gave an address on "Feeble-mind Children," in which he pleaded strongly for legislati on behalf of this class in Ireland. He pointed o that the investigations of the Royal Commissi of 1906 had been followed by ameliorative Acts Great Britain, which were not made to apply Ireland, although the need was relatively grea in Ireland. In the Irish Free State there were t two institutions for the care of feeble-minded childr Throughout the country, hitherto, numbers had be consigned to the workhouses, where accommodati and treatment were of necessity inadequate, or to t asylums. There were no arrangements for the separa teaching of these children, and hence the necessa educational treatment they should receive formed part in the training of the teachers.

PUBLIC HEALTH SERVICES

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1929 statistics of six counties:—

Name of district and estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Hampshire .. (432,600)	16·5	12·7	0·77	1·43	2·2	2·7	56	28	3·7
Norfolk .. (322,990)	15·4	13·4	0·76	1·67	2·3	2·4	60	22	4·4
Leicestershire (295,300)	17·0	12·3	0·99	1·37	2·4	2·0	57	35	4·8
Northampton-shire .. (216,500)	14·3	12·2	0·83	1·50	1·8	2·3	55	19	4·8
Cumberland (208,720)	17·7	13·3	0·88	1·48	2·6	2·4	74	34	3·8
Holland .. (89,400)	19·4	13·1	0·67	1·59	2·3	1·8	63	24	3·4

Stillbirths per 100 live births: Hampshire 3·7, Leicestershire 3·6, Northamptonshire 3·2, Cumberland 3·6.

Hampshire.

Dr. H. Leslie Cronk shows that most of the districts in the county are still served by medical officers of health who are engaged in private practice, so that the Local Government Act, 1929, with the consequent redistribution of county districts, will entail great changes by the appointment of whole-time medical officers of health and also by the abolition of the combined appointment of sanitary inspector a surveyor. The County Council will be able to tak hand in the provision of satisfactory water-suppl and drainage for small districts which at pres lack such. It already does useful work under t Housing of Rural Workers Act.

Changes have been made in the scheme un which expectant mothers when booking midwi can insure against the need for medical help. first pregnancies the premium is raised to 7*s.* 6*d.* a the insurance does not become effective until c month after the payment of the premium. T midwives attended 78 per cent. of the confinemen The percentage of calls for medical help was 42 insured and 28 for uninsured cases. The net c to the Council for each insured case was 7*s.*, and each uninsured 4*s.* 8*d.*, and the total net cost w £1684. Experience in Winchester has shown that t maternity beds needed for emergency and abnorm cases are approximately equal, and the beds need for these two groups are estimated at 44. T 40 abnormal cases admitted into the Hampsh County Hospital, Winchester, were: 22 of dispropo tion, 5 of toxæmia, 3 of antepartum hæmorrha and 10 others. All the mothers did well, but 4 the children were stillborn. The 47 emergency ca admitted to the same hospital were 19 of toxæm 13 of obstructed labour, 10 of antepartum hæmorrha and 5 others. One mother died and the remain did well. Of the toxæmia births, 8 were stillbo (2 macerated); of the obstructed labours, 7 we stillborn; and of the antepartum hæmorrhage, 5 we stillborn. The septic cases admitted under t Council's scheme numbered 29, of which 23 we received into the special isolation block of the Coun Hospital, and 6 to three other hospitals. New arrang ments are in progress with regard to the four group of cases—namely, normal cases, where t home conditions are unsatisfactory. The services an approved consultant were asked for in ten cases

uerperal pyrexia and fever, six of whom were mitted to hospital. An investigation of the after-stories of cases of ophthalmia neonatorum, notified uring the last two years, shows that in 1928 one ild was blinded in one eye and one in both eyes, id that in 1929 one child was blinded in one eye id two children in both eyes.

Dr. Cronk is doubtful as to whether a campaign r immunisation of children against diphtheria ould be pushed, but he thinks that general prac-tioners should be in a position to offer immunisation those who desire it. A summary is given of the olation hospitals provided by the 17 urban and rural districts, and a scheme has been prepared for e elimination of unsatisfactory small hospitals and e concentration of beds in as few centres as possible.

There are in the county 2800 producers of milk. here is no routine veterinary inspection of the dairy rds, and the taking of milk samples for the discovery tuberculous udders has not passed the experimental age.

Norfolk.

Dr. T. Ruddock West states that it is hoped during 30 to establish a comprehensive maternity and ild welfare scheme, including health visiting and idwifery services, throughout the county. The mber of parishes without a midwife in 1929 was 6, as compared with 186 in 1928. The births in e county numbered 4967. Midwives attended out half—1221 in their capacity as midwives and 85 as maternity nurses.

In July, 1929, the medical, dental, and nursing aff of the school medical service were transferred to e public health department, and as the clerical staff as transferred in the previous year, the unification the public health service is now complete. The ublic health committee has approved a scheme for e provision of isolation hospitals. The County ouncil already owns a site of 14 acres at East reham, with drainage, water-supply, electric light, s, and land for extensions available, and a hospital ill be erected on this site, which will provide for all stricts at present without accommodation. The ovision to be made for small-pox is still under nsideration.

Under the orthopædic scheme there are two inspec-on clinics—at Norwich and King's Lynn—con-ucted by the orthopædic surgeon, Mr. M. W. Bulman. he doubling of the cases seen as compared with the evious year shows that ascertainment is improving. reatment clinics would be difficult to establish in is thinly populated county, and the treatment is at esent given in the home by the (whole-time) ortho-edic nurse, Miss J. E. Kemp, under the instructions the orthopædic surgeon. The County Council ntributes towards the apparatus required. At the d of the year there were 126 pre-school-children on e register, including 69 cases of rickets and 28 of ngenital deformities. The tuberculosis officers use e services of orthopædic nurse, and call in the thopædic surgeon when required. Twenty-two berculous children were using surgical apparatus at e end of the year. About 100 school-children also tended the two orthopædic clinics during the year. ort-stay hospital cases are accommodated at the nny Lind Hospital, Norwich, and long-stay cases the orthopædic hospitals at Pyrford and in London. There is a pressing need for accommodation for dvanced pulmonary and surgical tuberculosis, which is hoped will be met by the sanatorium to be tablished on the Stanninghall Estate of the County ouncil.

Leicestershire.

Dr. J. A. Fairer reports that an epidemic of small-ox began in July in the Shepshed and Ibstock stricts, spreading to the western side of the unty and to areas in the vicinity of Leicester. hicken-pox was prevalent at the same time and in e Shepshed district the first cases of small-pox hich occurred were not recognised for some weeks. he notifications received numbered 230, and there were no deaths. The two county hospitals were opened for the reception of patients in July and August respectively, and also admitted 62 cases from the city of Leicester. Of the 268 cases admitted, 246 had never been vaccinated, and among the vaccinated remainder there were no cases under the age of 35. There are three permanent and four temporary hospitals provided by the County Council for infectious diseases. Some of these are inadequately equipped and will be replaced by a combined sanatorium and isolation hospital to be erected at Markfield, in which there will be 54 beds for infectious diseases. In January the services of the county oculist, Dr. Constance Walters, were made available for pre-school children, and spectacles were prescribed for 11.

There were 362 notifications of diphtheria with 34 deaths, a case-fatality of 10·6. The deaths ascribed to influenza were 81 in the urban areas with a population of 120,900, and 156 in the rural areas with a population of 174,400. There are now 42 maternity and child welfare centres under the auspices of the County Council, as compared with 18 ten years ago, but antenatal work is only just beginning. The births numbered 5013, and the two antenatal clinics were attended by 39 and 53 mothers respectively. There are three hospitals and five out-patient clinics available for orthopædic work, but the need is pointed out for more systematic organisation in order to obtain continuity and to avoid over-lapping. Dr. H. J. Blakesley, who conducts the male V.D. clinic at Leicester Infirmary, reports a serious outbreak of virulent syphilis—there being 82 cases in the primary stage as compared with an average of about 15 for the past three years. Most of the cases showed a virulent form of actively infective organisms in addition to the spirochæte.

The River Soar was in a very polluted condition during 1929, owing partly to the excessive drought.

Northamptonshire.

Dr. J. M. Mackintosh took over the duties on Jan. 1st, 1930, following on the resignation of Dr. L. Meredith Davies in November, while Dr. Lila S. Greig acted during the interim. The report shows that the notification of births is incomplete. Of the 3104 live births, 242 were unnotified and of the 98 stillbirths only 61 were notified. Of 128 infant deaths investigated by the health visitors 77 died in the first month and 43 of the 77 were said to be prematurely born. In addition to the 15 maternal deaths, which make up the rate of 4·8, 6 other deaths investigated (on behalf of the Ministry) were associated with childbirth, one being a death from pelvic peritonitis due to attempted abortion. There were 14 cases of puerperal fever and 30 of puerperal pyrexia. In some cases the illness appeared to be concurrent only with the puerperium, and in one case infection was possibly due to a douche of milk and water given by a handywoman. Hospitals in Kettering, Stamford, Rugby, and Northampton are available for these cases and the same hospitals with the addition of the Warwickshire County Maternity Home for confinement cases. The last-named cases, numbering 48 during 1929, are those with unsuitable home accommodation and those whose confinement is likely to be abnormal.

Orthopædic treatment is provided in the county by the Manfield Hospital with its several out-patient centres. There were 29 known cases of small-pox with no deaths and 227 cases of diphtheria with a case-fatality of 5·7 per cent. There is a decrease in the attendances at the tuberculosis dispensaries but a large increase in the number of patients visited at home in consultation by the tuberculosis officer. The situation as to the examination of contacts is unsatisfactory. Young children are brought up by their parents, but young adults from 15 years onwards cannot be induced to attend. A very high proportion of pulmonary cases are only notified when hopelessly ill, and the hospital accommodation for advanced cases is quite insufficient. The tuberculosis officer,

Dr. G. B. Lord, also asks for hospital beds to enable artificial pneumothorax to be carried out satisfactorily.

Cumberland.

Dr. F. H. Morison says the noteworthy feature of 1929 was the fact that for the first time a complete maternity and child welfare scheme was put before and accepted by the County Council and only awaited the sanction of the Ministry of Health. Cumberland relatively to population, has made more use of the Housing (Rural Workers) Act than most counties. Forty-three applications have been received since last year and grants were sanctioned in every case. One application was subsequently withdrawn. The total assistance promised since the inception of the Act has amounted to £6745, about half of which has been already paid in respect of 67 dwellings.

Mr. R. Simpson, F.R.C.V.S., makes his second annual report on the inspection of the dairy herds. An increase of the veterinary staff has been sanctioned as it has not been possible to get round all the herds on the register. No opportunity is lost to educate producers not only in the hygiene of cattle but in the production of clean milk. Six outside complaints of tuberculous milk were received and three notices as to tuberculous milk in the county. In the investigation of these nine cases, the offending cow was discovered at the first examination in six instances. In one case the cow involved was detected and slaughtered in the district of another local authority. In the eighth case the result was negative, probably owing to the sale of cows, and in the ninth case the sample was from a large milk depôt which derived supplies from other counties and a negative result was obtained in the three Cumberland farms involved. The County Council have also instituted routine bulk sampling of milk in order to test for cleanliness and the presence of tubercle. Two hundred such samples were taken of which one-third reached the rather low standard for cleanliness, and three samples (1·5 per cent.) were tuberculous. The cows discovered and slaughtered with tubercle of the udder numbered 19, those with tuberculous emaciation 58, and those with other definite signs 66. Two cowkeepers were fined £5 each for failing to notify tubercle of the udder in an advanced stage, and another owner was fined £10 for failing to report a cow with advanced generalised tuberculosis. Mr. Simpson is of opinion that all the duties in connexion with designated milk should be carried out by the local authority.

Dr. Morison again complains of the inadequate arrangements and equipment of the V.D. clinics held at the Cumberland Infirmary, Carlisle, and at the Whitehaven and West Cumberland Hospital.

Holland.

Dr. H. C. Jennings shows that influenza affected the statistics adversely. The death-rate was 1·9 more than in 1928, and the infant mortality-rate 17 higher. Boston Borough had an infant-rate of 103 and Boston Rural one of 84. Diphtheria was more prevalent and 158 out of the 206 cases occurred in Boston and neighbourhood with 11 deaths. One of the 13 survivors from ophthalmia neonatorum suffered impairment of vision. Orthopædic clinics are to be held in the county in order to save the long journeys of patients to outside hospitals. The tuberculosis-rate was lower than ever before, but the rate in Boston is double that for the rest of the county. The dispensary is successful in securing the attendance of contacts for examination, and there are 30 open-air shelters loaned out to patients. Inquiries were made as to four confinements attended by unqualified women, and the need for a midwifery service subsidised by the County Council in the sparsely populated districts is pointed out.

On the night of Nov. 12th to 13th huge quantities of dead and dying fish passed down the River Witham as the result of gross pollution from the sugar beet factory at Bardney. The proprietors of the factory were prosecuted and fined £50, and it is understood that the effluents are to be treate according to the most modern practice in order t prevent recurrence. In January, 1929, a region water committee was formed, and as a result a schem for the water-supply of the whole district at a cost £320,000 has been prepared by Sir Alexander Binnie Son, and Deacon. A report by the county M.O.H. dated Sept. 5th, 1929, shows the water-supply Boston to be grossly polluted. At that date th beck supplying the storage reservoir had been dr since June and the reservoir had become a pond stagnant water. The new supply is to be derive chiefly from the Bourne springs which are borehole sunk into a bed of the lower oolite, known locally a Lincolnshire limestone. Additional pumping plan will be needed to increase the supply from thes boreholes.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDE AUGUST 23RD, 1930.

Notifications.—The following cases of infectiou disease were notified during the week:—Small-pox 93 (last week 95); scarlet fever, 1471; diphtheria 953; enteric fever, 67; pneumonia, 474; puerper fever, 52; puerperal pyrexia, 97; cerebro-spina fever, 13; acute poliomyelitis, 15; encephaliti lethargica, 6; dysentery, 4; ophthalmia nec natorum, 101. No case of cholera, plague, or typhu fever was notified during the week.

The number of cases in the Infectious Hospitals of th London County Council on August 26th–27th was a follows:—Small-pox, 209 under treatment, 4 under observa tion (last week 183 and 3 respectively); scarlet feve 1632; diphtheria, 1810; enteric fever, 32; measles, 157 whooping-cough, 84; puerperal fever, 17 (plus 7 babies) encephalitis lethargica, 119; "other diseases," 25. A St. Margaret's Hospital there were 13 babies (plus 9 mother with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, includin London, there was no death from small-pox, 3 (0) fro enteric fever, 5 (0) from measles, 2 (0) from scarle fever, 11 (1) from whooping-cough, 28 (11) fro diphtheria, 45 (13) from diarrhœa and enteritis unde two years, and 19 (1) from influenza. The figures i parentheses are those for London itself.

The deaths from enteric fever outside London occurre at Birmingham, Nottingham, and Oldham. No great tow reported more than 1 death from measles or whooping-coug Liverpool reported 3 deaths from diphtheria. Diarrhœ was responsible for 9 deaths at Liverpool, 3 each at Birmin ham and Manchester.

The number of stillbirths notified during the wee was 292 (corresponding to a rate of 42 per 100 births), including 49 in London.

ST GEORGE'S HOSPITAL.—The annual repo of this hospital records that 5120 in-patients we treated last year. Their average stay was 22 days, and the cost £15 0*s.* 8*d.* each. The 39,432 new out-patients co 7*s.* 1*d.* per head. There were 250 births and 4286 oper tions, and 733 discharged patients were sent to Atkinso Morley's Convalescent Hospital at Wimbledon. A ver large increase is reported in the work of the electrother peutic department. The income was £85,492 and th expenditure £86,483. The cost of maintenance is now mo than double that of 1913.

THE NEW BETHLEM HOSPITAL.—In his annua report Sir Lionel Faudel-Phillips, the treasurer of th Royal Hospitals of Bridewell and Bethlem, states tha the completion of the transfer of patients and the ope ing of the new buildings at Monk's Orchard will be a accomplished fact in the course of next month. Last ye there were 416 patients, a smaller number than usua because of the decision to close the hospital at Lambeth new admissions before the reopening at Monk's Orchar The average weekly cost per patient on ordinary expenditu was £4 13*s.* 9*d.*, but of the total cost (£46,312) £15,073 w provided by payments for patients varying from 2 to guineas a week; 20 per cent. of the patients are on th free list.

CORRESPONDENCE

ULFOSIN THERAPY IN GENERAL PARALYSIS OF THE INSANE.

To the Editor of THE LANCET.

SIR,—Patterson and Switzer [1] have reported on ulfosin Therapy in General Paralysis of the Insane, d they think that they did not obtain such a arked pyrexia as was to be expected according to hroeder's paper. To this I may say that it seems take some experience to obtain a maximal tempera- re with this treatment. For it has happened over d over again that physicians have written to me this respect when they were first taking up the lfosin treatment, but later, when I have instructed em in details on this point, they have always been tisfied with the results they obtained. It is my perience that the most favourable and reliable lfosin effect is obtained by deep intramuscular jection—i.e., *supraperiosteally* on the lateral surface the femur—preferably after a brief heating over a all flame (alcohol burner), by which means the lfosin is dissolved completely. In this way I have ployed the sulfosin therapy in 14 cases of general ralysis, and in 100 per cent. of these cases I obtained emperature of or above 39° C. (102·2° F.), and in per cent. of the cases a temperature of or above ° C. (104° F.), leaving out the first two injections in ch series that were given as test injections for the justment of the dose.

In fact, the various authors who have worked with is therapy (Shilvock,[2] Harris,[3] Marcuse and allmann,[4] Stiefler,[4] Jacobson and Smith,[4] Insabato [4]) ve been satisfied with the pyrexia obtained—nay, 15 patients Armenise [5] did even obtain a temperature or above 40° C. (104° F.) in 13 cases (87 per cent.). The pyrexia obtained with the sulfosin treatment ay, therefore, be said to be satisfactory, and it bears ry well comparison with the pyrexia of the malaria erapy. In addition, some authors (Warstadt,[4] res [4]) have found that several cases which had oved refractory to the malaria therapy were sponding to the sulphur treatment.

Besides, the pyretic effects of the malaria and the lphur treatments may hardly be compared by a mple tabulation of the maximal temperatures btained. For the pyrexias are not identical in the alaria and the sulphur treatments. The temperature rve in the sulphur therapy differs considerably from e temperature curve in malaria therapy; in the lfosin therapy the rise of temperature is of shorter ration than the fall, which frequently runs a mittent course, giving an unusually wide curve that characteristic of the sulfosin effect. Indeed, it as been shown that the improvement in the humoral actions is more pronounced in the sulfosin therapy an in the malaria therapy.

As to the inconveniences in the sulfosin therapy, I all willingly admit that the reaction after the sulphur jection—in particular when it is effective—is companied by some pain at the site of injection. s a rule this pain does not set in immediately after e injection, but most frequently some hours later, may be not until the temperature begins to rise. Generally these pains subside fairly rapidly, but tenderness and pains may persist for some days. These symptoms are treated with hot compresses (or alcohol compress) or electrical thermos-pillow, later on with massage. There is a great deal of individual difference in the sensitiveness to these pains, which unfortunately appear to be unavoidable if a favourable therapeutic effect is to be obtained. I have met with these pains in the response to every one of all the sulphur preparations I have tried out, and I have attempted, but in vain, to eliminate them in various ways—for instance, by injecting cocaine together with the sulphur. I have arrived at the conclusion that these pains are to be accepted as indicating that the organism is responding to the treatment with the desired reaction. As a rule the patients put up with these pains placidly and look upon them as an unavoidable discomfort. For these pains are by no means unbearable. This is evident from the fact that I have treated children of all ages without having to discontinue the treatment on account of pains.

I am, Sir, yours faithfully,

KNUD SCHROEDER, M.D.,
Physician-in-Chief to the Odense Hospital.

Odense, August 29th, 1930. Denmark.

FATAL SYNCOPE FOLLOWING PERCAIN ANALGESIA.

To the Editor of THE LANCET.

SIR,—The following case of cardiac syncope during the induction stage of a percain intraspinal block should be recorded. A woman, aged 50, suffering from a very large multilocular ovarian cyst occupying the abdomen up to the costal margin, was given an injection of 14 c.cm. of 1 : 1500 percain in 0·5 per cent. saline, spec. grav. 1·003, between L1 and L2, and then placed in the prone position in order that the posterior roots should have a sufficient concentration of the drug. About three and a half minutes after being placed in this position she suddenly collapsed and died. She was turned on her back, the abdomen was opened, and the cyst punctured to relieve pressure on the diaphragm, and cardiac massage was performed with the usual restorative measures, but without success. The post-mortem examination revealed nothing remarkable in the heart.

This case shows without doubt that any attempt at the prone position in such cases is a tactical error. The weight of the trunk must very greatly increase abdominal pressure, and the contents may be thrust upwards against the diaphragm and pericardium. Furthermore, it is possible that the great vessels may be pressed between the spinal column and the tumour with great embarrassment to the circulation. It was the opinion of Dr. H. B. Weir, who conducted the autopsy, that the adverse mechanical conditions resulting in this case were the probable cause of the syncope. The amount of percain injected—between 0·009 and 0·01 g.—is so small that a general toxic effect can be excluded. One of the chief advantages of percain is that the amount required for spinal blocks is only a small fraction of the maximum dose permissible for infiltrations (0·2 g.).

The fall of blood pressure which occurs after spinal injections would be a contributory cause, especially in a case of this nature. For this type of case the prone position should, therefore, be abandoned, and

the patient may instead be kept for five minutes in each lateral position, with the head end of the table slightly lowered as a precaution. As percain injections are likely to prove useful in operative obstetrics, it is as well to remember that the gravid uterus presents a similar contra-indication to the prone position. With regard to normal administrations, the prone position has given rise to no difficulty, and a steadily increasing number of cases have been uniformly successful. No case has shown any involvement of cervical nerve roots.

I am, Sir, yours faithfully,

W. HOWARD JONES.

London, W., August 26th, 1930.

UNDESIGNATED PASTEURISED MILK.

To the Editor of THE LANCET.

SIR,—The annotation on milk-borne epidemics in your issue of August 16th (p. 359) mentions the pasteurisation of milk in Brighton. The one-third of Brighton's supply which I included as pasteurised is treated in every way as designated pasteurised milk would be. The pasteurisation is done not at the farm but by a few large distributors; thereafter the milk is bottled and capped before being handled, so that the risk of infection after pasteurisation is reduced to a minimum. This year infected milk from a farm was sent both to an urban area and to Brighton. An outbreak of scarlet fever resulted in the urban district, but not in Brighton; fortunately the Brighton supply was pasteurised by the retailer before distribution. This is a good practical example of the benefit of the process.

I quite agree with you that it would be better if all pasteurised milks were sold as designated milks, and when the public have realised the comparative safety of drinking pasteurised milk the retailers who pasteurise will sell their milk as designated milk. In the meantime the public, and indeed even doctors, are confused by the number of designated milks, and are not taught that the safest liquid milk from the point of view of tuberculosis and sore-throat infections is pasteurised milk.

I am, Sir, yours faithfully,

DUNCAN FORBES,
Medical Officer of Health, Brighton.

August 20th, 1930.

THE MEDICAL TREATMENT OF CANCER.

To the Editor of THE LANCET.

SIR,—We, in Liverpool, have long regretted Dr. Todd's somewhat—shall I say—irritating attitude in regard to our investigations, but we have endeavoured to treat him with every consideration, for we know—indeed he, himself, has stated this in print [1]—that he has felt that enough notice was not being taken of his publications. I am grateful to you, Sir, for tactfully correcting, in your leading article, the ridiculous insinuations which are contained in the following statement made by Dr. Todd: "This [Dr. Todd's] research *was commenced in 1925, shortly after the revival or rehabilitation* of the lead treatment of cancer was brought about at Liverpool. Lead is an old remedy for cancer; Ambroise Paré used it with success, and we (the plural used to include the team) have obtained some results from a modification of his method." (Italics mine.) Does Dr. Todd wish to imply that I have been guilty of plagiarism, and that he has followed Paré and not us? This would be a step forward in Dr. Todd's pretentions that his work is quite independent of ours. Admittedly, Dr. Todd *commenced his work three years after our first publication*, which was the result of many years previous research. An interval of three years can hardly be described as "shortly after," to use Dr. Todd's words. Nevertheless, Dr. Todd in his first paper in 1927, and in his larger publication in 1928 acknowledged what we had done. It will be noted that his first paper appeared in the fifth year after our first communication to THE LANCET.[2] In this interval of five years we had published many other papers and addresses.

I had no knowledge, any more than Dr. Todd had, of the various, generally very curious, uses of lead in the treatment of "cancer" and other diseases made by early writers until Thomas's paper in French (1928) was brought to my notice, although I have referred to the knowledge of lead poisoning in ancient times. Indeed, if I had it would have interested me not at all scientifically, for doubtless every element has at one time or another been applied empirically and some as panaceas for superficial lesions of all kinds. My reason for using lead was scientific and original, and will, I think, be so regarded by all fair minded persons. Must we, I would ask Dr. Todd, regard the Good Samaritan and other benevolent persons of olden days, who used alcohol as a lotion for wounds, as the pioneers of antiseptic surgery? However, those interested will see some of this ancient history set forth on pages 388 et seq. of our book "Some Aspects of the Cancer Problem." Perhaps this was the source of Dr. Todd's information. If so he seems to have missed, or failed to profit from, the introductory paragraphs to that section, which are as follows:—

> "The interest created by our work in the treatment of malignant disease with lead has led to a search through the literature, ancient and modern, to discover whether the remedy is a new one. The common fate, indeed, of all original work on a considerable scale is that it shall first be tested in respect of its value; then, if it be of proved worth, the literature from the time of the Ebers papyrus (circa 1500 B.C.) must be searched lest priority be claimed. This is right and proper, provided the historian has critical faculties." And the later sentence: "It does not appear that any indication was discovered of the special action of lead on malignant neoplasia until our own work was commenced in the year 1919; indeed, it may be stated with confidence that there is little in the literature to lead one to suppose that before the clinical work was started in Liverpool in 1920 any serious and scientific attempt had been made to treat malignant disease with lead."

I hope I shall never again be called upon to perform the distasteful task of meeting such a charge.

There are, too, certain matters of fact in Dr. Todd's paper and in your leading article on which I may be allowed, perhaps, to say a few words. From first to last we have advocated (the references can easily be found by anyone interested) the coincidental use of calcium and iodine. We have combined both of these in some of our preparations, and have always administered calcium lactate independently. A large supply of parathormone was sent to us from America soon after it had first been made, and we have used it in certain cases. So, too, with liver extract; for a long time we have employed this for the prevention and treatment of anæmia; and radiosterol we have used for infected cases. I do not know that we have especially referred to the last three in print, but they and other adjuvants, have been employed not only by ourselves but by others when there have been indications. We believe that any practical physician would consider the exhibition of the last-named preparations as merely incidental.

The serious manner in which the writer of the leading article deplores the present state of the general medical treatment of cancer fills me with

concern. Even without lead so much can be done to relieve many patients, and I thought such methods were common in practice. The suggestions made to surgeons by Dr. Todd, which are summarised in the last paragraph of your leader, are all included in our paper which was published in THE LANCET in 1922.

It is interesting to learn, however, that Dr. Todd has discovered the error he made in denouncing the combination of lead and radiotherapy,[3] which we advised in our first paper. On the publication of Dr. Todd's first communication I wrote to him privately to call his attention to the fact that the "decidua" is not the "trophoblast," as he appeared to think. In my opinion, there is no excuse for a repetition of an error. Again, what does Dr. Todd mean when he writes in his present paper, page 391, column 2: "In addition, we found that the normal fat-splitting enzyme of the blood, which was usually increased in late cancer, showed a diminution when the treatment was being effective." When he made this statement on a previous occasion I again wrote privately to inform him that the augmentation of the pancreatic enzyme by the serum of cancer patients is reduced, as first shown by Shaw-Mackenzie, not increased—as Dr. Todd says—and that the administration of lead to these cases tends to restore this activity to the normal, and this is especially evident when they are doing well. My colleagues, Prof. Lewis and Dr. Corran, have published papers on this subject.[3 4] In our opinion, Dr. Todd's statements concerning this matter are the converse of the true state of affairs. Further, it is unfortunate that Dr. Todd should select a calcium compound to produce acidosis for the purpose of the prevention of lead storage. Acidosis certainly causes the liberation of ionic lead, but calcium actually leads to its storage, and we are in the habit of exhibiting calcium lactate for this purpose in order to avoid toxic manifestations, and have injected calcium chloride intravenously to mitigate these. Dr. Todd also tries to persuade his readers that we believe that the action of the lead is local only; I have frequently said that it acts constitutionally as well as locally, and this is based on experimental work, all of which has been published. Indeed, the researches of Prof. Lewis and Dr. Corran just mentioned indicate that beneficial changes are produced by lead in deranged body functions associated with cancer. We have, too, presented evidence that the action of lead is also local. This was evidently clear to the reviewer of our book, "Some Aspects of the Cancer Problem," in the *British Medical Journal*,[5] for he writes:—

> "The exact way in which lead deleteriously affects the cancer cell is not dogmatically stated, but it is thought to be probably both local and constitutional."

There is another point in regard to the general clinical aspects, both in Dr. Todd's paper and in your leading article which requires notice. Stress is rightly laid on relief in the disease as well as on cure. With regard to alleviation, I have time and again pointed out that this must be taken into account in any assessment of the value of lead therapy. On page 421 in our book mentioned above, the following sentence contained in a paper published in 1929 will be seen:—

> "Again, it cannot be too forcefully reiterated that in the early application of any new method, however important an absolutely curative effect may be, *arrest and alleviation of the disease must equally be taken into account. . . .*" (The italics are in the original.)

Nevertheless, clinical cures, such as we have obtained, are the ideal at which to aim, for obviously if they can be obtained alleviation will be more sure in the rest of the cases. Dr. Todd has apparently obtained no clinical cures of the disease.

As to lead selenide, to which Dr. Todd has almost exclusively devoted his attention, we have made this and other preparations of lead and selenium, and have found that the selenide has little value in comparison with other preparations. Lead selenide has not much, if any, abortifacient action; it has a low chemotherapeutical value, and, in our opinion, cannot be relied upon to affect malignant growth, hence the limited success of Dr. Todd. It is, in fact, not a preparation that should be employed to-day, for there are many better; indeed, this has been so from the commencement of our work. I hope soon we shall be able to say something about the more recent organic preparations made by Prof. Heilbron and Dr. Beilonsohn, which have given us good experimental results, and have, apparently, a satisfactory chemotherapeutical index.

For the sake of many patients who, if they knew the truth, would more readily submit to treatment, I must make it quite clear that in our hands it is very rare for any reaction at all to be produced by intravenous injections of lead preparations, and certainly injurious effects never occur at the present time. We have not seen a serious reaction for some years. There is a general impression abroad, and this is fostered by opponents of our methods and, I have reason to believe, by Dr. Todd himself, that severe reactions inevitably follow treatment administered by us. This is not so. Our preparations are as atoxic as lead selenide, and are very active, not comparatively inert as is lead selenide. Dr. Todd mentions, and in your leading article reference is made to, smaller dosage. In this connexion I would quote from a paper I published in 1928, as published in "Some Aspects of the Cancer Problem": "We have tended gradually to decrease the individual doses while aiming steadfastly at the administration of a high total quantity of lead—that is, 0·5 g. to 0·8 g. or a little more. . . . From this we may provisionally conclude that it is advisable to continue in a modified form the treatment over a longer period of time than previously considered necessary."

I am sorry to have to write this letter, but in view of all that has happened in connexion with our work it is necessary to insist that at least the truth be told, the literature be studied, and the work efficiently conducted, otherwise lead therapy in malignant disease will suffer at the hands not only of critics but also of friends.

I am, Sir, yours faithfully,

Liverpool, August 30th, 1930. W. BLAIR BELL.

RADIUM AND LEAD SELENIDE COMBINED.

To the Editor of THE LANCET.

SIR,—Dr. A. T. Todd has recently stated in your columns (August 23rd, p. 389) that radium treatment of cancer after lead selenide treatment not only has no retarding influence on the tumour growth, but causes tumours which had been held in check by lead selenide to spread rapidly and shorten life. He mentions 12 cases, but gives no details of how the

radium was applied. From this he argues that radium treatment has no direct action on the tumour cells, not even a retarding influence on their growth; and that the adverse influence of radium treatment is entirely a secondary effect. In view of the importance of this, perhaps we may ask exactly what X ray or radium treatment did these 12 patients have, and was the dose adequate? Recently at the Radium Institute there have been two patients who had several months' treatment with lead selenide, during which tumour growth ceased, but in which the tumours had not disappeared; they were given radium treatment (as under) with excellent results.

1. Male, aged 52, squamous epithelioma of neck. Lead treatment Sept. 20th, 1929, to March 20th, 1930. Tumour measured then 6·6 × 7·0 cm. On March 20th, 19 gold seeds 0·5 mm. gold, 1·8 mc. each, were inserted into the tumour, which rapidly disappeared, and on July 2nd patient was still free of disease and in good health.

2. Male, aged 54, secondary glands both sides of neck. Squamous epithelioma. Lead selenide Oct. 29th, 1929, to Dec. 18th. Aluminium seeds inserted into both sides on Jan. 1st, 1930, and 28th, when the tumours measured 5·5 and 6·0 cm. in diameter. On Feb. 17th the tumour on the right side measured 3·5 cm. and the left 5 cm. On July 2nd the right had disappeared, and the left was still growing. On July 14th the latter was again seeded.

It appears, therefore, that radium treatment after lead selenide treatment is not always followed by disastrous results.

We are, Sir, yours faithfully,

PHILIP GOSSE,
J. C. MOTTRAM.

TREATMENT OF PULMONARY TUBERCULOSIS IN SWITZERLAND AND AT HOME.

To the Editor of THE LANCET.

SIR,—I cannot agree with some of your correspondents that Dr. Harrison has overstated the facts. He has apparently a very intimate knowledge of the conditions of a winter cure in Switzerland, and although his statements may not apply to all patients or to all cure stations in the Alps, he has, speaking generally, drawn a very suggestive picture of the life of the average tuberculous patient wintering there. But there is one point which has not been stressed by any of your correspondents. I refer to the apparent declimatisation produced by a prolonged stay in Switzerland. Patients on their return home are more likely to relapse than those treated in our home sanatoria. They are more liable to catarrhal affections of the lungs and, as everybody knows, these affections are too often the forerunner of a process of reactivation in the old focus. If the patient finds that Switzerland suits him well, and if he is in a position to go out there winter after winter or, better still, if he is able to stay out there altogether, well and good. But if it is a question of six months there and back again to work in our "climate of perpetual damp and mist," then it is as well for him to undergo the treatment in a British sanatorium.

Dr. Amrein has not helped his case by his reference to "our perpetual damp and cloudy atmosphere." There are many localities from Land's End to John o' Groats where there is on the yearly average less mist and fog than in some of the best known "cure" stations in Switzerland. I have lived in the Upper Speyside district of Inverness-shire for the last 11 years, and I can say without fear of contradiction that I have seen less fog and mist in those 11 years than I saw for two winters spent in one of the most noted and best advertised Swiss resorts.

When the case is one where a very high altitude is indicated, and where the patient has to work for his living, I know of no more suitable climate than Southern Rhodesia. Entry is not difficult, provided the patient is sufficiently fit and is not likely to become a burden on the colony. For the last ten years I have sent many patients to Rhodesia after a preliminary cure here; most of them have made their homes out there, and the letters I receive from them are very encouraging.

I am, Sir, yours faithfully,

Kingussie, August 26th, 1930. FELIX SAVY, M.D.

TONSILLOMYCOSIS.

To the Editor of THE LANCET.

SIR,—In the early part of last winter I came across a fungus in a culture from the throat of a young woman. I did not recognise the condition until I read Castellani's article on tonsillomycosis in the January number of the *Practitioner*. Since then I have met with one other case, referred by Dr. Martin Edwards as a diphtheria suspect. This was a young man living on a croft. The tonsils, soft palate, and uvula were all patchy with creamy membrane, which peeled off leaving a slightly ulcerated surface. Direct smears showed monilia, and on blood-agar I got an almost pure culture. The chief symptom was unusual soreness on swallowing. Painting with solution of silver nitrate cleared it up in a day or two.

I am, Sir, yours faithfully,

JAMES CAMPBELL, M.B., Ch.B.

Lerwick, Shetland, August 16th, 1930.

INTRABRONCHIAL DRAINAGE.

To the Editor of THE LANCET.

SIR,—As is so rightly pointed out in your leading article of August 9th (p. 303), the mechanical factors in the course and treatment of such cases as bronchiectasis are of the greatest importance. One feels they require perhaps more attention than is given to them often, especially in the matter of mechanically assisting the patient to clear his chest. The bronchial blockage, the tenacity of the secretion, and the comparatively inefficient expulsive power from the bases of the lungs must all be taken into consideration. The poor emptying power of the lungs is usually helped by getting the patient to cough whilst leaning over the back of a chair, for instance, and this certainly helps, but it is not enough when one considers the bronchial obstruction and the thick tenacious fluid. Bronchoscopic methods are the only efficient and direct aids to the removal of the purulent material.

Of bronchoscopic instruments Chevalier Jackson's are the most satisfactory for this work on account of their lightness, good lumen, and practical adaptation to the needs that may arise. Those with proximal illumination, however, such as Haslinger's, have the advantage of throwing a powerful light well ahead of the distal end of the tube, so giving a good illumination of the area to be approached. Bronchial blockage and the filling of the tubes with fluid are the main causes of the distressing coughing. This blockage may be due to granulations or stricture, and in many cases both these can be treated through the bronchoscope with considerable relief to the patient. As Jackson has pointed out, the fluid from the lungs is often of such a viscid nature that it cannot be poured out of a reversed test-tube. In fact, when one sees the fluid, one wonders how it is ever coughed

from the bases of the lungs. Aspiration through a bronchoscope at regular intervals is the only satisfactory method of removing this material, and helps the patient greatly.

Aspiration helps to avoid the overflowing and flooding of other parts of the lungs mentioned in your leading article. One can picture the fluid being mixed up by the act of coughing, some reaching the larynx and some falling back into or being driven into other parts of the lungs. Direct aspiration seems to be a much neater process. Lavage through the bronchoscope is not good treatment, but vapours may be introduced.

I am, Sir, yours faithfully,

C. HAMBLEN THOMAS, F.R.C.S.

Harley-street, W., August 25th, 1930.

CARBON DIOXIDE FOAM BATHS.

To the Editor of THE LANCET.

SIR,—It has been our privilege to discuss Foam Therapy with a number of Medical men interested in the Article by Dr. Shillito on Carbon Dioxide Foam Baths published in your issue of June 28th,

With reference, in this connexion, to the Equipment required, may we ask for space in your columns in which to qualify Dr. Shillito's statement when he says: . . . "All that is now required to carry out this treatment is a Foam Distributor obtained either in this Country, *or, more cheaply, Abroad*" . . . &c.

We wish to make it clear that this Company holds British Letters Patent which cover the preparation of a *Double Layer Bath* of Water and Physical Foam. Therefore, any person who produces in England a Double Layer Bath such as Dr. Shillito describes, or other means than a Sandor Distributor (of which we also own the entire British Patent Rights) for the purpose of giving treatment, is thereby infringing these Patent Rights.

It follows that any Doctor who buys Abroad an Appliance for the production of a Double Layer Foam Bath, and uses it for giving treatment in his professional capacity in this Country, is equally injuring our Patents.

And so you will see, that when Dr. Shillito informs our readers that they can buy suitable Apparatus Abroad, he is suggesting, unwittingly of course, a procedure which they would not wish to follow when in full possession of the facts.

For your information, we would refer you to British Letters Patent Nos. 305030 and 280208.

We are, Sir, yours faithfully,

for SOAPLESS FOAM LIMITED,

D. CORNFORTH,

Manager.

17–18, Dover-street, London, W. 1., August 22nd, 1930.

MIDDLESEX HOSPITAL.—The 1929 report refers to the lead given by opening beds specially for radiological treatment of cancer. The system of not waking patients before A.M. has been adopted by over 100 hospitals here and in distant lands. More than two-thirds of the reconstruction scheme had been completed at the end of last year, and a number of private rooms for paying patients have already been opened. Building operations reduced the number of beds available, and the in-patients numbered 5607, as compared with 6271 in 1928. This loss of beds increased the cost per head, which was £5 4*s.* 8*d.* against £4 15*s.* 1*d.* in the preceding year. Out-patients numbered 54,400, an increase approaching 2000. In the cancer wing 870 patients were treated, an increase of 158, which, as the number of beds is the same, is accounted for by shorter stays. The individual cost of these patients was £6 6*s.* 11*d.*

STILLBIRTHS AND INFANT MORTALITY.

INTERNATIONAL INQUIRY.

THE inquiry made during 1927–28 by the Health Organisation of the League of Nations[1] into the causes of stillbirths and infant mortality during the first year of life has not been merely into the statistics but into the medical, social, and hygienic aspects of the subject. Investigations were made in Austria, France, Germany, Great Britain, Italy, the Netherlands, and Norway, by methods as far as possible uniform; and since it was impossible that the investigators should attend all confinements in the selected districts, information was obtained through notification by competent authorities, and, in cases of death, by application to the doctor, the midwife, the family, the welfare centre, or any other institution which the mother had attended. The social inquiries were made through the visiting nurse, officials in the registrar's office, clergymen, or other persons well acquainted with the environment of the family, as well as by visits to the home. Information relative to the child's family, the child, and the confinement was obtained by means of a uniform inquiry form which took account of the housing conditions, the morbid history of the family during the life of the child, the obstetric history of the mother, the care and feeding of the infant, the history of the fatal illness, and any personal observations of the investigator.

The infant mortality of the various districts was classified under the headings: low, moderate, high, and very high, and the investigation was made over a period of a year in every case. The investigation in Italy was begun later than elsewhere, and is not included in this analysis.

District Mortality.

Districts with a low infant mortality.—In Great Britain, where the inquiry was conducted by Dame Janet Campbell, a low infant mortality was found in Oxfordshire, and within the same range—3·5 to 4·9 per cent.—fell Hedmark and Oslo West (Norway), and Leiden and Dordrecht (Netherlands). Oxfordshire and Hedmark are both agricultural districts where the housing conditions were found to be poor, the hygienic conditions on the whole favourable, and breast-feeding the usual rule. In Oxfordshire two-thirds of the women received antenatal supervision, but in Hedmark this was rare and child welfare organisation inadequate. Dordrecht, Leiden, and Oslo West, urban districts with a commercial population, shared favourable housing and hygienic conditions, numerous and well-patronised medical institutions and welfare clinics, and a preponderance of breast-fed infants.

A moderate infant mortality—5 to 6·9 per cent.—was found in Croydon and Staffordshire (Great Britain), Breda, Maestricht and Emmen (Netherlands), Lochois and Chinonais (France), Lippe (Germany), and Oslo East (Norway). Rural districts included Staffordshire, Lochois and Chinonais, Lippe, and Emmen, and conditions varied considerably between them; in Staffordshire, for example, the population is semi-agricultural and semi-mining, housing was found to be rather poor, child welfare work well organised, antenatal supervision sought by about one-half the pregnant women, and breast-feeding commoner than artificial. In Lochois and Chinonais, with a wine-growing and agricultural population, and

[1] Memorandum C. H. 820. Obtainable (3*s.* 6*d.*) from George Allen and Unwin, League of Nations Department, 38, Great Ormond Street, London, W.C. 1.

moderate or satisfactory housing and hygienic conditions, child welfare organisation was seen to be little developed and antenatal supervision rare; pregnant peasant women were frequently overworked, but confinements are always conducted by a doctor or trained midwife; breast and artificial feeding maintained equal proportions. In Lippe, also an agricultural district, housing and hygienic conditions are regarded as favourable on the whole, but social conditions often bad; half the female population work, and though antenatal supervision is rare, child welfare organisation is good and breast-feeding common. In Emmen the housing conditions are in places often very bad, and unemployment is prevalent; the birth-rate is high and breast-feeding common, while child welfare and antenatal clinics are only now in the process of organisation. Contrasted with these are the four urban districts with a moderate infant mortality, which show a certain uniformity of conditions. In all except Maestricht the housing conditions are fairly good, and antenatal and child welfare work well organised; breast-feeding was said to be common in all except Croydon.

Districts with a high infant mortality—7 to 9·9 per cent.—included Sunderland (Great Britain), Pays de Caux and Plaisance and the Zone of Fortifications (France), Cassel and Augsburg (Germany), Vienna, districts VI., VII., and VIII. (Austria), and Hoensbrock (Netherlands). Pays de Caux, mainly agricultural, showed bad housing conditions, poorly developed child welfare and antenatal organisations, unskilled midwifery, and defective feeding of infants; Hoensbrock, the other rural district in this group, is devoted chiefly to mining; the housing conditions are favourable, and infant welfare clinics exist but are little used. The remaining districts in this group, all of which are urban, have housing conditions which vary from poor to deplorable, except in Cassel, where they are moderately good, and offer child welfare and antenatal facilities of a high order in all; in the majority of these areas the pregnant women work, in some cases excessively.

A very high infant mortality (10 per cent. and over) was found in Pays de Bray (France), Stelitz (Germany), and Gmunden, Schärding and Engelhartszell, and Vienna, district X. (Austria). All of these, except the Vienna district, are agricultural, and mostly the population shows a low standard of intelligence. Work is common and often excessive among pregnant women, and the child welfare or antenatal centres are either limited or absent, and are seldom well attended; infant feeding is usually defective and frequently artificial; midwifery often reaches a poor standard, and illegitimacy is common. In Vienna, district X. the living and social conditions were found to be bad, and pregnant women often overworked; infant welfare work, however, is well organised.

Principal Causes of Death.

The principal causes of death among infants were classed under digestive disturbances, respiratory diseases, and stillbirth, either due to premature delivery, obstetrical trauma, or some other cause. By far the largest number of deaths were due to respiratory diseases, either as an individual condition or following one of the specific fevers which also played a considerable part in raising the infant mortality. Premature birth, and death from unknown causes were responsible for the highest figures in many districts, while digestive disturbances took a less prominent position in every case. It was found that, in areas where the infant mortality was high, specific infections reached a considerable figure as a ca[use], while in districts with a low mortality they w[ere] practically non-existent.

Conclusions and Recommendations.

The investigators conclude that in districts wh[ere] the mortality is low and child welfare clinics [are] abundant and well organised, the incidence of respi[ra]tory and infectious diseases and digestive disturban[ces] falls considerably, while the rates for stillbirths a[nd] infant mortality during the first weeks of life rem[ain] practically the same everywhere. The preventi[on] of stillbirth, they consider, depends largely [on] efficient antenatal care and the early diagnosis [of] malpresentations, toxæmias of pregnancy, syphi[lis], or other conditions which permit of prophylax[is]. They therefore recommend the establishment of m[ore] antenatal clinics, the supervision of the pregn[ant] woman in industry, and a campaign against t[he] employment of unskilled midwives. They also sugg[est] that financial and other forms of assistance to pregn[ant] women should be extended, so as to permit them [a] rest during the latter months of pregnancy, and th[at] social measures should be applied impartially [to] legitimate and illegitimate children. The need [for] more institutional provision and for the more thorou[gh] instruction of doctors and midwives in the care of t[he] infant are emphasised; as a preventive measu[re] against digestive disturbances and respiratory a[nd] other diseases the extension of child welfare clin[ics] and the better instruction of the public in possi[ble] modes of infection are advised.

MEDICAL NEWS

Medical Society of London.

The syllabus for the first half of the 158th session beg[ins] with a presidential address on the Stethoscope, Past a[nd] Present, by Dr. R. A. Young, to be given on Oct. 13, following the annual general meeting of the Society. the Monday evening discussions that on the prophylac[tic] and therapeutic values of vaccines will be introduc[ed] (Oct. 27th) by Sir Almroth Wright; on the diagnosis a[nd] treatment of malignant disease of the chest (Nov. 10th) Prof. Chevalier Jackson; on the pathological conditions the eye due to inflammatory changes in other parts of t[he] body (Dec. 8th) by Mr. A. F. MacCallan and Mr. Ern[est] Clarke. Nov. 24th will be a clinical evening. The Llo[yd] Roberts lecture on Painting and the Healing Art will delivered on Wednesday, Nov. 19th, by Prof. Willia[m] Rothenstein, M.A. The Lettsomian lectures next spri[ng] are to be given by Dr. J. W. McNee on the Spleen, Structures, Functions, and Disorders. The annual orati[on] of the Society will be delivered on May 11th, 1931, by [Sir] John Rose Bradford.

St. George's Hospital Medical School.

On Wednesday, Oct. 1st, at 3 P.M., Lord Riddell will gi[ve] an inaugural address at the annual prize distribution the Board Room of St. George's Hospital. Dr. Jam[es] Collier will take the chair at a dinner to be held on t[he] evening of the same day at the Hyde Park Hotel, Knigh[ts]bridge.

Society of Medical Officers of Health.

A provincial meeting of this society will be held at t[he] Grand Hotel, Lowestoft, at 4 P.M., on Friday, Sept. 19t[h]. The subject of discussion will be the Public Health Significan[ce] of General Medical Service Schemes, and the speakers w[ho] include: Dr. Astley Clarke, senior physician, Leicester Roy[al] Infirmary; Dr. C. E. S. Flemming, member of Consultati[ve] Council, Ministry of Health; Dr. H. P. Newsholme, M.O.[H.] for Birmingham; and Dr. A. M. N. Pringle, M.O.H. f[or] Ipswich. Members will later be entertained to dinner [by] the Mayor and Corporation of Lowestoft, and on t[he] following afternoon there will be a launch trip on Oult[on] Broad. Members who intend to be present are asked notify the executive secretary at 1, Upper Montagu[e] street, Russell-square, London, W.C. 1, by an early po[st]

Chelsea Clinical Society.

The annual dinner of this society will be held at the Rembrandt Hotel on Tuesday, Oct. 28th, at 7.30 P.M.

Paddington Medical Society.

The next meeting of this society will be held on Tuesday, Sept. 9th, at the Great Western Hotel, Paddington, at 8 P.M., when Dr. E. G. Graham Little, M.P., will give an address entitled Private or Contract Practice?

Royal Sanitary Institute.

The forty-second congress and health exhibition of this Institute will be held at Glasgow from July 4th to 11th, 1931, under the presidency of Sir Henry Mechan.

Radium at Bradford.

The Health Committee of Bradford Corporation has been given official permission to borrow £20,000 for the purchase of radium for St. Luke's Hospital.

King's College Hospital.

The in-patients last year numbered 7006 and cost £10 15*s.* 5*d.* per head; the 41,684 out-patients cost 12*s.* 9*d.* each. The number of patients received into the hospital was the highest since the war. The income was £100,677, and the expenditure £101,821; the debt amounted to £65,867. The annual report refers to the world-wide reputation obtained by the urological department founded in 1922, and to the enormous development of the physical treatment department. A clinic was founded for the investigation and treatment of asthma and allied diseases, and now has more than 100 cases for detailed study.

King's College Hospital Medical School.

This school has now completed a hundred years' work, and an account of this will be given by Dr. Raymond Crawfurd, on Oct. 1st, at the opening ceremony of the winter session, when Dr. G. F. Still will preside. The centenary dinner, at which Sir StClair Thomson will take the chair, will be held on the same evening at the Connaught Rooms. It is proposed to mark the centenary by completing the Medical School buildings as soon as the necessary funds can be collected.

Liverpool Open-Air Hospital for Children.

This hospital at Leasowe, in Cheshire, last year discharged 96·6 per cent. of tuberculous cases "disease quiescent." Of the 110 cases so discharged in 1926, 94 per cent. are now known to be fit; in 1927, 84·8 per cent.; in 1928, 90·6 per cent. An interesting section of the report deals with the 224 cases treated by artificial light. While the results, it is thought, do not prove that artificial light has any specific action upon cases of tuberculous disease, combined general and local irradiation assists and hastens recalcification during convalescence and the healing of sinuses, and shortens the stay in hospital of cases of tuberculous adenitis and peritonitis.

Florence Nightingale Fund.

The annual report states that during the year 78 probationer nurses were admitted from the preliminary training school to the Fund's school at St. Thomas's Hospital, and 51 nurses completed their term of service and were awarded certificates. Miss Lloyd Still, matron of St. Thomas's, and superintendent of the Nightingale Training School, received 1159 applications for the regulations and accepted 163 applicants. From the opening of the school in 1860 to the end of 1929 2434 names were placed on the register of the Nightingale Nurses to be added ultimately to the hospital staff. At the end of the year 37 of these nurses were holding positions as matrons. The income of the fund was £2192 and the expenditure £1988.

Hospital Libraries.

At its conference at Cambridge, from Sept. 22nd to 27th, the Library Association will consider, among other subjects, the provision of libraries for hospitals. Besides a paper on the history and practice of this work in Great Britain, there will be papers from Denmark and the United States. Miss Ostenfeld will read a paper on Collaboration between Public Libraries and Hospitals in Denmark, and will open a discussion on the possibility of applying similar methods in this country. A second paper on the Psychological Value to Patients of Hospital Libraries will be read by Miss Perrie Jones, hospital librarian at St. Paul's, Minnesota, U.S.A. Further particulars may be had from the secretary of the Library Association, 76, Bedford-square, London, W.C. 1.

At the recent Empire Conference of the British Red Cross Society a resolution was passed approving "The Principle of Reading as part of Curative Medicine," and desiring to see it established in all hospitals in due course.

St. Mary's Hospital Medical School.

The annual dinner of past and present students will be held at the Trocadero Restaurant at 7 P.M. on Friday, Oct. 3rd. Dr. Reginald Fuller will take the chair.

New Operating Theatre at Keswick.

Sir John Randles is presenting a new operating theatre, to cost some £4000, to Keswick Hospital. It is to bear the name of Lady Randles.

Oxford Mental Defectives.

Subject to certain consents, Wyfold Court, near Henley-on-Thames, from which Lord Wyfold takes his title, is to be purchased by the Oxford City Council as a home for mental defectives.

Royal Dental Hospital of London.

The prize distribution and conversazione of this hospital and school of dental surgery will be held at the hospital in Leicester-square at 8 P.M., on Thursday, Oct. 2nd. Sir John Rose Bradford, F.R.S., will preside.

A Hunt Hospital Bed.

Mr. H. R. Turner, who has given a bed to the Devonshire Hospital, Buxton, has named it "The High Peak Hunt Bed." Mr. Turner, who is one of the joint masters of the hunt, desires that the bed should be associated with the farmers of the country.

Rebuilding Corbett Hospital.

It is proposed practically to rebuild the Corbett Hospital at Amblecote, Stourbridge, at a cost of £150,000, of which one-third would be provision for maintenance. Between £17,000 and £18,000 has already been subscribed, and it is hoped that substantial assistance will be forthcoming from the John Corbett Trust Fund.

New Doncaster Infirmary.

When the Earl of Lonsdale opened the new Royal Infirmary at Doncaster, he received purses containing more than £4000. The building has cost £156,000, of which £103,000 has been raised; it is the first portion of a scheme for an institution of 300 beds.

Red Cross Clinic for Rheumatism.

The British Red Cross Society's clinic for the treatment of rheumatism (Peto-place, Regent's Park, London, N.W. 1) has been reopened after a month's closure for internal reconstruction. The accommodation has been nearly doubled to meet an unexpectedly large demand. In future, the clinic will be open from 8.30 A.M. to 9.30 P.M., and whereas men and women were formerly treated on alternate days, arrangements have now been made by which both sexes can come on the same day. Since the opening in March about 25,000 treatments have been given, and the attendances have steadily increased. Considerable use has been made of the clinic by private patients, and in July alone over a thousand treatments were given on the private floor. The system of booking appointments for all patients has worked well and will be continued. Five honorary visiting physicians, with 15 clinical assistants, are now at work at the clinic. The remainder of the staff consists of a medical registrar, the sister-in-charge, with sisters-in-charge on each floor to assist her, 15 masseuses, 10 masseurs, and a lady almoner and her assistants. In addition, six new consultants—a dental surgeon, a radiologist, an orthopædic surgeon, a throat specialist, a surgeon, and a gynæcologist—have been appointed. For patients belonging to approved societies a course of nine attendances costs 25*s.*, with subsequent courses if necessary at 20*s.* For private patients treatments cost half a guinea each, in addition to a consultation fee of £2 2*s.* 0*d.* to the consulting physician.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

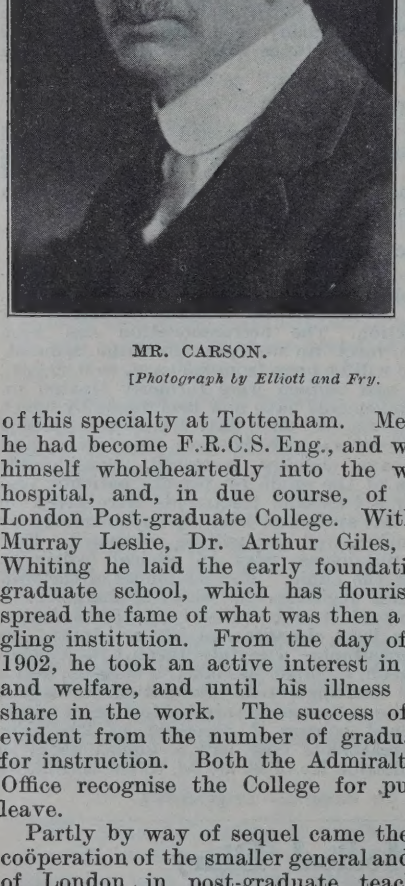
MONDAY, Sept. 8th, to SATURDAY, Sept. 13th.—QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal-Green, E. Special Course in Diseases of Children, occupying all day, with lectures and demonstrations. Syllabus and ticket of admission from the Fellowship of Medicine.

OBITUARY

HERBERT WILLIAM CARSON, F.R.C.S. Eng.

Mr. Carson's death at the age of 59 will be regretted not only by colleagues and collaborators, but by everyone who observed his devotion to post-graduate education and other desirable causes. He was a capable surgeon and a hard worker, and his services to the Prince of Wales's Hospital during the past 30 years were given by mind and heart without stint.

Born in 1870, Carson received his medical education at St. Bartholomew's Hospital, and qualified in 1895. His first appointment was that of house surgeon to the Tottenham Hospital (now the Prince of Wales's) and he returned there as assistant surgeon in 1897. At this time his bent was to towards ear, nose and throat surgery, and he served as clinical assistant at Golden-square, and in the throat department at St. Bartholomew's under Sir Anthony Bowlby before taking charge of this specialty at Tottenham. Meanwhile, in 1899, he had become F.R.C.S. Eng., and was able to throw himself wholeheartedly into the work of his new hospital, and, in due course, of the North East London Post-graduate College. With the late Dr. R. Murray Leslie, Dr. Arthur Giles, and Dr. A. J. Whiting he laid the early foundation of this post-graduate school, which has flourished and widely spread the fame of what was then a small and struggling institution. From the day of the opening, in 1902, he took an active interest in its development and welfare, and until his illness he had a large share in the work. The success of these efforts is evident from the number of graduates who attend for instruction. Both the Admiralty and the India Office recognise the College for purposes of study leave.



MR. CARSON.
[*Photograph by Elliott and Fry.*

Partly by way of sequel came the association and coöperation of the smaller general and special hospitals of London in post-graduate teaching under the Fellowship of Medicine. The grouping was based on a report and list prepared by the Tottenham group for the Athlone Committee, and during the greater part of the succeeding ten years Carson played an energetic part in the work of the Fellowship. This was arduous and often delicate. For many years he was unofficial honorary secretary for overseas, and in this capacity visited Canada in order to inform himself of the needs of medical men from the Dominions. Latterly he was chairman of the executive committee of the Fellowship, and kept thin moving by the impetus of his progressive personalit Recently he was appointed to the provisional organis tion committee of the new British Post-gradua Hospital and Medical School at Hammersmith.

As a surgeon, Carson's work was chiefly concern with the abdomen, but his interests remained genera He was the editor of—and a large contributor to "Modern Operative Surgery," published in 192 This appeared in two volumes and its design was exclude operations which have lost their usefulnes even if they are classics. In its preparation l secured the services of the younger generation surgeons and by enforcing the rule he produced valuable book within a reasonable compass. H also edited the tenth edition of Pye's "Surgic Handicraft." In the medical societies he was frequent speaker and displayed the same lucidity in his teaching. At various times he held th presidency both of the Hunterian Society and th Medical Society of London, and to these as to oth offices he brought enthusiasm and well-directe labour. In 1929 he travelled to America to delive the Mütter Lecture of the College of Physicians Philadelphia, taking Intestinal Obstruction as h subject, and treating it exhaustively from th historical, clinical, and operative points of viev During the late war, he held a captain's commissio in the Royal Army Medical Corps and served a surgeon to the King George Hospital.

Mr. Carson was married, but had no family. I leisure time he was a chess player, a keen crickete and a seafarer in small sailing boats. In person h was tall, well-built, soft of voice, and rather deliberat of utterance, and he had the gift of making friend Dr. A. J. Whiting as one of his colleagues a the Prince of Wales's tells us that it is not to much to say that Carson lived for the hospita "In all discussions of policy and procedure th crucial point with him was—what is best for th hospital? To those who know, or can read betwee the lines, it will be enough to say that he took a active part, or even a leading part, in two enlarge ments of the place, and was plunged in a third at th time of his death. Impetuous, genial, sometime rather ruthless, but with a well of tenderness not fa from the surface, he focused his attention on the objec of attainment rather than the foreground. But i he was forceful he was also lovable.

"He will be remembered not so much as good surgeon or a good hospital colleague, althoug he was both of these, or as an excellent teacher and he was that; but rather as a man of vivi personality and a stark worker. He manifeste to all, without any possibility of doubt, that th Prince of Wales's Hospital implied for him th Prince of Wales's motto."

CHARLES BUTTAR, M.D., D.P.H. Camb.

Dr. Buttar who died after an operation at Limecroft Guildford, on August 31st, was the son of Charle Buttar of Elgin Crescent, Notting Hill, by Emily daughter of James Lovett, of Cricklade, Wilts. He wa born in 1867 and was educated at Westminster Schoo and Pembroke College, Cambridge. In 1887 he gained a second class in the Classical Tripos and in 1889 he graduated, after obtaining a second class in

art I. of the Natural Science Tripos. He then roceeded to St. Bartholomew's Hospital and qualified 1892, taking the M.B. and B.Chir. Camb. the same year. In 1896 he proceeded to the .D., having been admitted M.A. in 1893 and king a D.P.H. in 1895. At St. Bartholomew's ospital he served as house surgeon for a year and as for a time assistant anæsthetist, after which he as appointed house surgeon to the Metropolitan ospital, subsequently becoming clinical assistant the Western Ophthalmic Hospital.

For many years Dr. Buttar carried on a large ractice in Notting Hill and Kensington, living tterly at Inverness-terrace until he retired to elstead in Essex. So long as he lived in London he ook an active part in the affairs of the British Medical ssociation and being a first-rate organiser and an cellent man of business, he acted during the war chairman of the Executive Committee of the Central edical War Committee, a body which was entrusted ith the delicate duty of deciding which members the medical profession could be spared for duty road; when the medical needs of the Army and avy were at their greatest there was a dangerous pletion of the medical men required to serve the untry at home. The Committee over which he esided, which was charged to hold the balance, had acuter or fairer member than its chairman. ie same qualities of tact and discretion were splayed at the Harveian Society, where he was in ccession secretary, vice-president, president in 1909, ustee and treasurer. He found the finances of the ciety in a bad state, but his energy and capacity abled him to hand over the treasurership to his ccessor Dr. G. de Bec Turtle in the flourishing ndition in which they have since been maintained. Dr. Buttar was also an active member of the Council Epsom College. He married in 1898 and had e son.

JOHN THOMSON WILSON, M.D., D.P.H. Aberd., J.P.

Dr. J. T. Wilson died on August 20th at his home Bothwell, Lanarkshire, at the age of 75. He d retired on grounds of health some years ago t maintained his interest in medical affairs.

A native of Cambuslang, in Lanarkshire, Wilson aduated in medicine at Aberdeen in 1891 and oceeded to the M.D. degree five years later, with a esis on the Natural History of Scarlet Fever. This as an elaborate and valuable statistical study and its neral conclusion that preventive measures have tle effect in limiting the disease has been, on the ole, verified. After serving as assistant medical icer in Shropshire for two years he was appointed unty medical officer for Lanarkshire in succession to e late Dr. James McLintock, who in 1894 became the st medical member of the Local Government Board Scotland. Lanarkshire is the biggest Scottish unty, with a population of about 300,000 rural and out 200,000 urban. Since Dr. Wilson's appointment asgow has annexed some of it, but the county ll remains the largest.

In the course of his long career as medical officer ilson commanded great influence because of his ssionate sincerity. He displayed a deep earnestness all that he undertook—which was a great deal. e organised his great department on lines to suit e developments of the future and the county is day reaping the benefit of his foresight. To any ident of the health movement in the Northern ngdom his elaborate annual reports were indispensable. Apart from these he produced two other striking pieces of work—namely, special reports on rivers pollution and on the housing of miners. The latter was one of five required by the Local Government Board as a preliminary to the work of the Royal Commission on Housing. All were excellent for their counties, but Wilson made his report both a groundwork for recommended reforms and an administrative survey of the whole mining area. It was of great use to the Royal Commission when members visited the numerous miners' rows and villages of Lanarkshire. The report showed what ought to have been done; the visit of inspection showed what had not been done. But the county has made up leeway and it would be difficult to name any place in Great Britain where, relatively, greater progress has been made. His devoted work over 30 years has ended in a body of institutions that any county may be proud of. Among them may be mentioned the Hairmyres Sanatorium and Work Colony established during his term of office.

Wilson was a scholar in the academic sense and he carried the detail of his work easily; but he felt very keenly the serious responsibility of the position. In addition he took his full share in the work of the Royal Sanitary Association of Scotland, the Society of Medical Officers of Health, and other bodies and held examinerships at Aberdeen and Edinburgh Universities.

Dr. Wilson's wife survives him.

Appointments

ADAM, JAMES R., M.B., Ch.B. Edin., D.P.H. Edin. and Glas., has been appointed Medical Officer of Health for the county of Roxburgh.

BROWNLIE, JAMES LAW, M.D., Ch.B. Glasg., D.P.H. Camb. (at present County Bacteriologist and Pathologist in Lanarkshire), has been appointed a Medical Officer of the Department of Health for Scotland.

DUGAN, ALEXANDER M., M.B., Ch.B. Aberd., D.P.H. Aberd., has been appointed Assistant Medical Officer of Health for School Medical Services in Aberdeen.

THOMAS, ALFRED TREVOR GWYN, M.B., B.S. Durh., has been appointed one of the Surgeons on the *Mauretania*.

Certifying Surgeons under the Factory and Workshop Acts: AITKEN, J. (Wainfleet District of the County of Lincoln); COXON, H. C. (Newburn District of the County of Northumberland); CREASER, F. G., M.B., B.Ch. Edin. (Snaith District of the County of York, W.R.); THOMSON, G. L., M.B., Ch.B. Glasg. (Tighnabruaich District of the County of Argyll).

Vacancies

For further information refer to the advertisement columns.

Albert Dock Hospital, Connaught-road.—M.O. At rate of £110.
All Saints' Hospital for Genito-Urinary Diseases, Vauxhall Bridge-road, S.W.—H.S. At rate of £150.
Ascot, Heatherwood Hospital.—Res. Asst. M.O. £300.
Barnsley, Beckett Hospital and Dispensary.—Jun. H.S. £140.
Bath, Royal United Hospital.—Asst. H.S. At rate of £120.
Bedford County Hospital.—H.S. £175. Also Asst. H.S. £130.
Birmingham General Hospital, Anæsthetist.—£120. Also three H.S.'s. £70.
Birmingham, Selly Oak Hospital.—Cas. O. £200.
Bradford City.—Asst. Bacteriologist. £600.
Brighton, Royal Sussex County Hospital.—Cas. H.S. £120.
Bristol Royal Infirmary.—Asst. for Cancer Research Laboratories. £400.
Cambridge, Addenbrooke's Hospital.—H.S. Also H.S. to Special Depts. Each at rate of £130.
Cancer Hospital, Fulham-road, S.W.—H.S. At rate of £100.
Cardiff, King Edward VII. Welsh National Memorial Association.—Area Asst. Tuberculosis Phys. £600. Also half-time Asst. Tuberculosis Officer for Pontypridd area. £300.
Cardiff Royal Infirmary.—Gynæcological H.S.—At rate of £50.
Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Hon. Asst. Anæsthetist.
Chesterfield and North Derbyshire Royal Hospital.—H.S. At rate of £100–£175.
Connaught Hospital, Orford-road, E.—H.P. At rate of £150.
Derby, Derbyshire Hospital for Sick Children.—Res. M.O. At rate of £150.

Dewsbury, New Dewsbury and District General Infirmary.—Jun. H.S. £150.
Dreadnought Hospital, Greenwich.—H.P. and H.S. Each at rate of £110.
Dulwich Hospital, East Dulwich-grove, S.E.—Third Asst. M.O. £300.
Eastcote, Middlesex, St. Vincent's Orthopædic Hospital.—Res. M.O. At rate of £150.
East Ham Memorial Hospital, Shrewsbury-road, E.—Res. M.O. At rate of £200. H.P. At rate of £150. H.S. At rate of £120.
Evelina Hospital for Children, Southwark, S.E.—H.S. At rate of £120.
Glasgow University.—Dr. Robert Pollok Lectureship in Materia Medica and Therapeutics.
Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—Second H.S. At rate of £120.
Great Yarmouth General Hospital.—Sen. and Jun. H.S.'s. £150 and £140 respectively.
Guildford, Royal Surrey County Hospital.—H.S. £150.
Guy's Hospital Dental School, London Bridge, S.E.—Teacher of Conservative Dental Surgery. £1000.
Halifax Royal Infirmary.—3rd. H.S. £150.
Hospital for Tropical Diseases, Endsleigh-gardens, W.C.—Two H.P.'s. Each at rate of £150.
Ilford, King George Hospital.—Res. M.O. £250. Also House Officer. £100.
Infants Hospital, Vincent-square, Westminster.—Two H.P.'s. Each at rate of £75.
Inverness District Mental Hospital.—Jun. Asst. M.O. £350.
Ipswich, East Suffolk and Ipswich Hospital.—Cas. O. £150. Also H.S. At rate of £120.
Kingston-upon-Hull, City and County of, Beverley-road Institution.—Asst. M.O. £300.
Lanark, County of.—Bacteriologist and Pathologist. £750.
Lancashire County Council.—Asst. County M.O. £800.
Lancaster County Mental Hospital.—Asst. M.O. £350.
Leeds Public Dispensary.—Jun. Res. M.O. £150.
Liverpool and District Hospital for Diseases of Heart.—H.P. At rate of £52.
Liverpool Royal Children's Hospital.—Second Res. M.O. At rate of £120.
Liverpool Stanley Hospital.—H.P. and H.S. Each £100.
London Female Lock Hospital, 283, Harrow-road, W.—H.S. £150.
London Hospital, E.—Surgical First Asst. and Registrar. Also Medical First Asst. and Registrar. Each £300.
London Lock Hospital, 91, Dean-street, W.—H.S. At rate of £200. Also Two Surg. Regs. Each £100.
Macclesfield General Infirmary.—Res. H.S. At rate of £180.
Madras, Medical College, Vizagapatam.—Professor of Pathology. 1100 Rs. per month.
Manchester, Ancoats Hospital.—H.S. At rate of £100.
Manchester and Salford Hospital for Skin Diseases.—H.S. £100.
Manchester, Baguley Sanatorium.—Asst. M.O. £350.
Manchester, Royal Children's Hospital, Gartside-street.—Two Asst. M.O.'s. At rate of £150.
Manchester, Royal Children's Hospital, Pendlebury.—Res. M.O. and Res. Surg. O. At rate of £125.
Manchester Royal Infirmary, Roby-street.—Jun. H.S. and Cas. O. £100.
Merthyr General Hospital.—Res. H.S. At rate of £150.
Miller General Hospital, Greenwich-road, S.E.—Cas. O. At rate of £150. Also H.P. and H.S. Each at rate of £125.
National Hospital, Queen-square, W.C.—Res. M.O. £200.
Northampton General Hospital.—H.P., 2 H.S.'s, and 2 Asst. H.S.'s.—All at rate of £150.
Nottingham Children's Hospital.—Res. H.S. At rate of £150.
Nottingham General Hospital.—H.P. Also 2nd Cas. O. Each at rate of £150.
Oldham Royal Infirmary.—Two H.S.'s. Each at rate of £175.
Park (Fever) Hospital, Hither Green, S.E.—2 Asst. M.O.'s. Each £500.
Plymouth, South Devon and East Cornwall Hospital.—Asst. Pathologist. £350.
Preston and County of Lancaster Royal Infirmary.—H.S. At rate of £150.
Princess Louise Kensington Hospital for Children, St. Quintin-avenue, N. Kensington, W.—H.S. and Cas. O. At rate of £75. Also Hon. Physician and Hon. Radiologist.
Reading, Royal Berkshire Hospital.—Cas. O. and Res. Anæsthetist. Each at rate of £150.
Royal Dental Hospital of London, Leicester-square, W.C.—Asst. Dental Surgeon.
Royal Eye Hospital, St. George's Circus, S.E.—12 Salaried Refractionists, 12 Clinical Assts., and 1 Pathologist.
Royal National Orthopædic Hospital.—H.S. At rate of £150.
Royal Northern Hospital, Holloway, N.—H.P., Res. Out-Patient Cas. O. and Anæsthetist. Each at rate of £70.
Ryde, Royal Isle of Wight County Hospital.—Vacancy on Hon. Med. Staff. Also Res. H.S. £180.
St. Bartholomew's Hospital, E.C.—Asst. Surgeon for Diseases of Throat and Nose. Also Asst. Surgeon to Orthopædic Dept.
St. Helen's Hospital.—H.S. £250.
St. Mary Abbots Hospital, Marloes-road, Kensington, W.—Asst. M.O. £250.
St. Mary's Hospital, W.—Physician in charge of Out-Patients.
St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—H.S. At rate of £75.
Salford Royal Hospital.—Two H.S.'s Each at rate of £125.

The Chief Inspector of Factories announces a vacancy for Certifying Factory Surgeon at St. Margaret's Hope (Orkney

Births, Marriages, and Deaths

BIRTHS.

AVERY.—On Aug. 25th, the wife of Dr. Harris Avery, of daughter.

CANE.—On August 23rd, at Reepham, Norfolk, the wife Dr. Maurice H. Cane, of a daughter.

KERRIGAN.—On Aug. 23rd, at Horrabridge, the wife of Surgeo Commander O. J. M. Kerrigan, R.N., of a son.

LLOYD.—On August 18th, at Avenue-road, Regent's Park, t wife of Eric Ivan Lloyd, F.R.C.S., of a daughter.

SPEIRS.—On Aug. 26th, at Walker-street, Edinburgh, the wi of Dr. R. C. Speirs, Tanganyika Medical Service, of daughter.

WHAMOND.—On August 19th, at Bentinck-street, W, the w of Captain W. D. Whamond, West African Medical Servi (Royal Army Medical Corps, retired), of a son.

MARRIAGES.

STEWART—DOS SANTOS.—On August 12th, at Knockbre Parish Church, Belfast, H. Hilton Stewart, M.D., M.R.C. Lond., to Clara Maria Luiza, daughter of the late M Antonio Luiz dos Santos and Mrs. dos Santos, of Rio Janeiro, Brazil.

WRIGHT—SHELDON.—On August 30th, at St. Andrew's Churc Cheltenham, Lieut.-Colonel Robert E. Wright, C.I.I I.M.S., M.D. Dub., to Ruby E. Sheldon, daughter of I S. T. Pruen, Cheltenham.

DEATHS.

AYTOUN.—On Aug. 28th, at Zermatt, Switzerland, while holiday, James Aytoun, B.Sc. (Hons.), L.R.C.P., M.R.C. only son of Dr. and Mrs. Aytoun, Broadstairs, Ke aged 23.

BALL.—On August 23rd, at Park-terrace, Oxford, John Augus Ball, M.B. Lond., in his 88th year.

BEVERLEY.—On August 31st, at Overstrand, Norfolk, Mich Beverley, M.D. Edin., M.R.C.S. Eng., L.S.A., J.P., in 89th year.

BUTTAR.—On Aug. 31st, following an operation, Charles Butt M.D., of Guildford, and formerly of Inverness-terrace,

CARSON.—On August 31st, Herbert W. Carson, F.R.C.S. En of Harley-street, Senior Surgeon, Prince of Wales's Gene Hospital, Tottenham, in his 60th year.

DOWN.—On Aug. 26th, at Whitchurch, Devon, Elgar Dow M.D. Durh., F.R.C.S. Edin., late of Plymouth, aged 63.

FINIGAN.—On Aug. 29th, Daniel O'Connell Finigan, M. Berlin, M.R.C.P. Lond., M.R.C.S. Eng., of West Sout bourne, formerly of Fordingbridge, aged 55.

HIGGINS.—On August 22nd, at the Shaftesbury Hotel, Liv pool, William Robert Higgins, M.D., F.R.C.S., of Brid street House, Louth, Lincolnshire.

KENT.—On August 18th, at a nursing home, Sydney Ke M.B., B.Chir. Camb., of The Corner House, Bexhill-o Sea, aged 65.

LITTLEJOHN.—On Aug. 27th, at Southwold, from heart fail while bathing, Thomas Plested Littlejohn, M.R.C. L.R.C.P. Lond., of Leigh-on-Sea, Essex.

MARTIN.—On Aug. 27th, at Atherton, near Manchester, Ma William Young Martin, M.B., Ch.B. Vict., late R.A.M (T.), aged 50.

SEYMOUR.—On August 18th, at his residence, Ambrose-aven Golders Green, George Seymour, L.D.S. Eng., of West E lane, N.W., aged 68.

TUKE.—On August 20th, at The Limes, Sutton Valence, Ma stone, George Montague Tuke, M.R.C.S., J.P.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices Births, Marriages and Deaths.

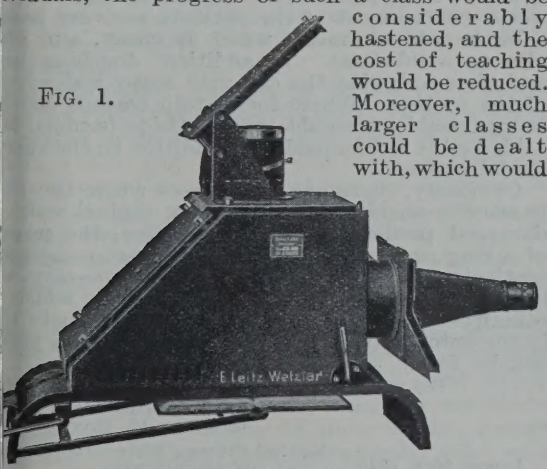
NOTES, COMMENTS, AND ABSTRACTS

AN APPARATUS FOR TEACHING LIP-READING TO LARGE AUDIENCES.

By CHARLES M. R. BALBI, A.M.I.E.E.,
ION. CONSULTING ELECTRICAL ADVISER TO THE NATIONAL INSTITUTE FOR THE DEAF.

)F the various available means of thought trans-ence for the stone deaf lip-reading is by far the st valuable, but it is essential that the "listener" ps a minute observation of the speaker's lips, ich at any distance is difficult. The conventions the deaf and dumb alphabet are still the most able means of intercommunication for the deaf, this system is useless when a deaf person wishes ommunicate with a person who has no knowledge the deaf and dumb code. Further, the language igns stamps the user as deaf, and the self-conscious son does not always care to give himself away by attempt at this sort of conversation. The next t method is perhaps writing, but the exchange vritten messages is cumbersome, and involves time. hird method of hearing through the sense organs ouch and vibration, vibrations being transmitted ough special "filter circuits" to a special receiver, been evolved by Mr. Robert H. Gault.[1] This hod does not seem to have been able to compete h the natural one of lip-reading, and hence it is irable to encourage this art where possible. ip-reading is usually taught individually, or if s taught in a class, each learner has the individual ntion of the teacher for a few moments. This advisable because, as already stated, it is ntial for the pupil to watch the speaker closely. it were possible to avoid this concentration on ividuals, the progress of such a class would be considerably hastened, and the cost of teaching would be reduced. Moreover, much larger classes could be dealt with, which would

FIG. 1.

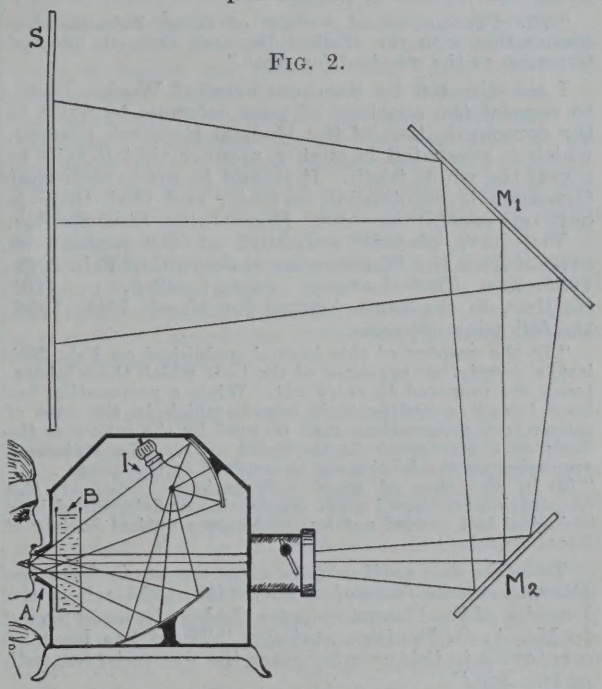


Apparatus for teaching lip-reading.

of great benefit to the deaf, since there is a great rtage of teachers of lip-reading.

The apparatus by which I have found it possible ulfil these requirements is very simple; it consists ely of a conveniently constructed epidiascope, ich has hitherto been used for reflecting illustra-is of books and specimens. With an apparatus dly lent to me by Messrs. Leitz and Co., ple proof was afforded that a teacher will be able instruct a large class; the movement of the cher's lips is reflected on to a screen and its area nlarged many hundredfold, and is easily followed n a distance. The apparatus on which my eriments were conducted (see Fig. 1) was not igned for reflecting parts of the living body; face of the speaker being so near the source of t is subjected to an intense light and heat, the ct of the heat being particularly disagreeable. With a larger (and hence more expensive) lens, the speaking distance from the source of light can be lengthened. This permits an alum bath to be inserted to absorb the radiant heat; the conducted heat is also much reduced at the greater distance, and the discomfort of the speaker would be abolished.

FIG. 2.



An optical system designed for enabling a large number of persons to lip-read from one source. A = aperture. B = alum bath. I = illuminating source. M_1 and M_2 = mirrors. S = screen.

Fig. 2 represents an optical system in which the disadvantages have been overcome. Study of the reflected image shows that the speaker's face will appear in vertical position, enlarged, but with the left side of the face transposed to the right and vice versa; but since the face is symmetrical, or sufficiently so for the purpose, the transposition does not affect those who are learning to read the movements thrown on to the screen. The mirrors (M_1 and M_2) can be placed at the back of the apparatus, and the screen (S) can be made of ground glass or some transparent material. The teacher speaks into the aperture A in the ordinary way, and the movements of his lips, which are reflected on the screen, are protected from the rays of the illuminating source I by the alum bath B. If it were decided to manufacture such an apparatus it should be possible to market it for about £100. In view of the saving in the teacher's time the question should be well worth considering. The apparatus could be used not only in schools but also in churches and lecture halls when the audiences are deaf.

BLENORETTES.

WE have received from Medical Accessories, Ltd., 92, Baker-street, London, W., a simple device which is intended to take the place of the unsatisfactory gonorrhœa bag. Blenorettes are cone-shaped water-proof reservoirs for fitting over the glans and are retained in place by zinc oxide plaster strips. Beyond a perforated felt-like disc the cones are filled with antiseptic gauze. Among the advantages claimed for this appliance are ease of application, firm fixture, and non-obstruction of the flow of discharge. The tips of the plaster strips are non-adhesive so as to facilitate removal.

"AN OFFICIAL CORRECTION FROM THE M.R.C."

To the Editor of THE LANCET.

SIR,—In your issue of August 16th (p. 361) you give prominence to an official statement by the Medical Research Council under the above title. The Council complain that misuse has been made of their name in a statement issued by our American house which reads as follows :—

"The Pharmaceutical Society of Great Britain, after consultation with the Medical Research Council, adopted Gynergen as the standard for ergot."

I am directed by Sandoz Chemical Works, Basle, to request the courtesy of your columns to reply to the communication of the Medical Research Council, which is presented in such a manner that it fails to reveal the whole truth. It should be made clear that Gynergen is ergotamine tartrate, and that there is only one ergotamine—viz., Ergotamine, Stoll-Sandoz.

You have already published at my request an extract from the *Pharmaceutical Journal* of Feb. 20th, 1926 (see THE LANCET, August 23rd, p. 410). Further, in the same journal for March 13th, 1926, the following appeared :—

"In the number of this journal, published on Feb. 20th last, a description appeared of the tests which these laboratories are prepared to carry out. When a preparation has been tested, a certificate is issued, which in the case of satisfactory preparations may be used by the maker as the basis of a statement on the label. . . . The statement appearing on the label must be confined to the words . . ." "(6) In the case of ergot perparations, c.c. of this preparation contains 1 mgm. ergotamine as determined by a biological test carried out by the Pharmaceutical Society of Great Britain."

To make the matter more clear we quote from the *Pharmaceutical Journal* of May 14th, 1927, where the Director of the Pharmacological Laboratories, replying to Mr. A. O. Bentley, stated : "There has been no ergotoxine in this country since the war until a month or two ago."

The reasons which caused the substitution of a salt of an amorphous alkaloid, difficult to purify, of lesser stability, less soluble, and which can only be conserved with difficulty (in vacuo over phosphorus pentoxide) for a definite, pure, stable, crystalline substance (base as well as salt) are probably not relevant here, but it is clear that ergotamine tartrate *was* adopted as a standard for ergot preparations, and that the Medical Research Council *was* consulted.

I am, Sir, yours faithfully,

"Sandoz" Scientific and Research Department, August 25th, 1930. J. FLINT, Manager.

THE LANCET has been asked by the Director of the Pharmacological Laboratories, Pharmaceutical Society of Great Britain, to publish the following note : "With reference to the extract from the *Pharmaceutical Journal* of Feb. 20th, 1926, published by you, at the request of the Sandoz Chemical Works, in THE LANCET for August 23rd, it should be realised that the statement was superseded by the announcement in the paper by Burn and Ellis, published in the *Pharmaceutical Journal*, 1927, vol. cxviii., p. 384, that 'Ergotoxine phosphate has been adopted as a standard for ergot.' A copy of this paper was forwarded to the Manager of the Pharmaceutical Department, Sandoz Chemical Works, 5, Wigmore-street, on June 8th, 1927, and I have his acknowledgement of its receipt."

HAY-FEVER.

A BOOK by Dr. R. M. Balyeat,[1] now in its third edition, tells the familiar story of protein sensitisation, and tells it avowedly to the patient rather than to the profession. It gives the life history, with illustrations, of such substances incidental to the asthma story as kapok and orris ; it gives illustrations too, of a horse, a cat, some dogs, and so on—even a young woman looking into a looking g to illustrate the use of orris. In short, the layr will find the book light reading, and need not deterred by fear of finding it too scientific or techni Some of the explanations of technicalities probably seem naive, even to readers little ver in technical nomenclature. For example : "' terms 'cutaneous' and 'dermal' will frequently used. They refer to the skin." It would be he handed to criticise the book too strictly from the a of the pathologist, but it seems a pity to use term "hay-fever" for any paroxysmal rhinorrh whether caused by grass pollen or not.

THE DUTCH PESSARY.

To the Editor of THE LANCET.

SIR,—The recent correspondence on the Dutch raises the important point of uniformity of stanc in fitting. Where the Dutch pessary is used, i suitable case, the Walworth technique is based the view that the maximum occlusion of the va is the object of its use, provided there is no harm or uncomfortable pressure. The size of the ca determined by the capacity of the vagina in quest The average size of the cap used at Walworth (wl most of the cases are mothers with several child is 72½.

The rim of the cap rests behind the pubic bon the anterior fornix, and posteriorly, its exact posi is largely determined by the length of the cervi short, high cervix permitting the rim to be tuc away into the posterior fornix.

The essential points in the use of this pessary (*a*) that the rim should be in contact with the va walls throughout its circumference ; (*b*) that it sh not be dislodged by moderate increase of in abdominal pressure, such as coughing and straini (*c*) that it should be perfectly comfortable to wearer. The spermaticide commonly used at V worth (where most of the patients are very poo a lactic acid ointment, which is cheap, and se also as a lubricant. In addition, douching be and after removing the cap with soapy water is of the routine. Where for certain reasons douc is inadvisable, a soluble spermaticide (semori, l acid, &c.) is recommended in addition to the sper ticidal ointment.

Obviously, there are many cases where the D pessary is unsuitable, such as lax vaginal walls damaged perineum, prolapsed uterus, the pres of a ring or Hodge pessary, and severe constipa (patients are warned not to use the pessary w they are constipated). In some cases which otherwise quite suitable, there is no adequate s in the anterior fornix in which the rim of the pes can be fixed.

We are, Sir, yours faithfully,

LILY C. BUTLER,
GLADYS M. COX,
Medical Officers, Walworth Wome
August 30th, 1930. Welfare Centre.

LONDON CHARITIES.

WE have received a copy of the thirty-eig edition of the Annual Charities Register and Dig which, as everyone knows, is a classified registe charities in or available for the metropolis. L alteration has been made in this edition excep bring the subject matter scrupulously up to d and the index is a model of completeness and venience. As on previous occasions the attempt been made to include only bona fide institutions societies, but the preface contains the usual war that the entry of an institution in the registe in its advertising pages is not equivalent to a ge recommendation of it. The editor solicits partic of institutions which are not mentioned in the pre issue ; these should be sent to him at Denison H Vauxhall Bridge-road, London, S.W.

ADDRESSES AND ORIGINAL ARTICLES

HERMAL ADJUSTMENT OF MAN AND NIMALS TO EXTERNAL CONDITIONS.*

By Sir Charles J. Martin, C.M.G., M.B., D.Sc., F.R.C.P. Lond., F.R.S.,

ECTOR OF THE LISTER INSTITUTE OF PREVENTIVE MEDICINE; PROFESSOR OF EXPERIMENTAL PATHOLOGY IN THE UNIVERSITY OF LONDON.

LECTURE I.

N these lectures I shall deal more particularly with conditions pertaining to warm climates. No empt will be made to give an equitable review of present knowledge of thermal adjustment or to alogue the immense number of researches which ve accumulated during recent years. After a liminary survey of the mechanisms of thermotaxis hall deal more particularly with some fragments of subject which have particularly interested me for wards of 30 years, and to the understanding of which ne small contributions have been made by my oratory comrades and myself.

Homœothermism signifies a measure of superiority environment, and the development of this faculty played an important part in the history of animal . When animals emerged from the sea they became victims of great and comparatively sudden changes temperature, for the rate of physiological proses, like that of the chemical processes underlying m, is influenced by temperature and to someat the same degree. Accordingly, unless an mal can control its temperature all its activities st rise or fall with the temperature of its vironment.

The information available on the effect of temperae upon various physiological activities was analysed Snyder (1908). It has also been collected by nitz (1915 and 1925). The rate of muscular traction and the velocity of nervous impulses, the rt-beat, and many other bodily functions are reased two or three times for a 10° C. rise. The uence of the temperature upon combustion in tissues of both cold-blooded and warm-blooded mals has been extensively studied, for oxygen sumption integrates the whole cellular activities the animal and is convenient to measure. fortunately, comparatively few of these experints have been made under standard conditions. ongst the most regular of these results, because urbing conditions (e.g., movements) were minied, are those by Krogh (1916). Krogh's observans cover a range of 8–28° C. with cold-blooded atures and 14–28° C. with the dog. He found in cases about 10 per cent. rise per degree Centigrade. s, at compound interest, amounts to 2·5 times for and 18 times the rate for 30° difference, a by no ans unusual variation in atmospheric temperature. gh found, however, that the increase is not so formly progressive as the logarithmic law for mical action implies, the rate of increase being ater at the lower temperatures. By establishing emperature around 40° which, from the materials which animals are constructed, provides the ximum activity attainable, the homœothermic mal achieved an immense advantage over its poikilothermic contemporaries. Whenever the surrounding temperature fell it could escape its cold-blooded enemies and catch its cold-blooded prey. This advantage is bought at the expense of fuel. The cost of bare existence of a lizard at 15°–20° is only about 2½ per cent. of that of a man reckoned for the same surface. Martin (1902.)

The economy of reptiles is indeed amazing. I was once called in consultation to see a python whose state of health was causing some uneasiness to its proprietors. It had not eaten for three years. As far as I could ascertain the only symptom was anorexia. I ordered forcible feeding and it was suggested that I should assist with the treatment. The creature proved to be so vigorous that we were unable to accomplish our object until we had cooled the animal with ice to 5° C., when we gave it 20 lb. of beef steak by means of a long pair of metallurgical tongs. Next day, when it warmed up, it defeated our efforts by regurgitating the meat. On inquiry a year later I heard that it had recently died of some intercurrent infection.

Mechanism of Homœothermism.

To keep a system at constant temperature throughout, any change of heat loss must be balanced by a corresponding change in heat production or vice versa. This necessitates a sensitive self-acting mechanism set to a particular temperature and capable of controlling either the rate of heat production or heat loss, or both. A regulator on the principle used in a thermostat, which turns on more heat if the temperature falls and turns it off if the temperature rises, would be the simplest mechanism and, if sufficiently sensitive, would work as long as the temperature of the body was considerably above its environment. But, as the environmental temperature approached that of the body, this mechanism would be inadequate to maintain a homœothermic state, for in an animal heat production cannot be reduced below a minimum consistent with life, and this minimum is multiplied five to ten times with strenuous work.

On the other hand, a regulating mechanism operating upon rate of loss alone would be very costly in fuel and thereby limit the range of external temperature within which a constant internal temperature could be maintained, and we find that higher mammals have achieved a compromise; they use both methods of regulation and different sorts employ them to varying degrees. Man, in his nakedness and the wide area over which he can sweat, is the best adapted of all creatures to withstand high external temperatures and, coincident with his loss of hair, his increasing intelligence has allowed him to extend the downward range of external temperature at which he could remain homœothermic by providing himself with adjustable insulation.

THE DIFFERENT MEANS OF HEAT LOSS AND THE PROPORTION DISPERSED BY EACH UNDER DIFFERENT CIRCUMSTANCES.

Heat is produced by combustion in the cells of the body. It is lost by radiation, convection, and evaporation. Apart from voluntary modification of his surface by posture and of his insulation, heat loss in man depends upon the temperature of his skin and the rate at which water is evaporated from

*The Croonian Lectures delivered before the Royal College of sicians of London on June 12th, 17th, and 19th.

it. These in any given atmospheric conditions are determined by the volume of blood circulating through the skin in unit time and by the activity of his sweat glands. Animals also voluntarily control loss of heat by posture and involuntarily by varying the thickness of their fur through erecting the constituent hairs, but in man "goose flesh" is an almost functionless vestige of this useful protective reaction. The proportion of heat lost by radiation, convection, and evaporation is determined by the temperature of the surroundings, the moisture in the air, and wind. It was estimated by Rubner (1896) that a man comfortably clothed and sedentary in a room at 15° C., the air of which is 50 per cent. saturated with moisture, loses 44 per cent. of his total heat dissipation by radiation, 31 per cent. by convection, and 20 per cent. by evaporation from lungs and skin. Aldrich (1928), by more modern methods, arrives at much the same conclusions. The proportion is very different if the surrounding temperature approaches or exceeds the temperature of the skin and if the sun shines upon him. Under these conditions loss by radiation and convection are minimised or heat transference by them reversed. Only evaporation is available.

A man even at rest produces about 1·2 large calories per minute, so he must, under these atmospheric conditions, evaporate at least 2 c.cm. of water per minute (each gramme of water evaporated absorbs 585 small calories) or 120 c.cm. per hour, even under the most advantageous circumstances for deriving all the heat required for evaporation from the body. With fairly strenuous work the heat produced will rise to five or six large calories, requiring a minimum of 600 c.cm. (approximately a pint) to be evaporated per hour, or his body temperature must rise. If he has to work in the sun and surrounded by objects hotter than his body, he will require to evaporate considerbly more, possibly twice as much. Hunt (1913) states that when doing survey work in India, with a shade temperature varying between 100° and 110° F., and walking about three miles per hour in the sun the minimum consumption of water per day was 3 gallons (30 lb.). I found great difficulty in impressing this simple arithmetical calculation upon military authorities during some of our desert campaigning in the summer of 1916.

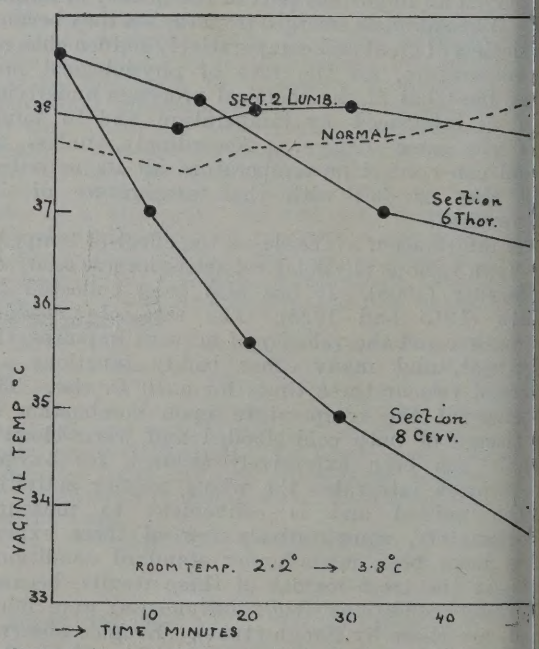
Nervous Mechanism of Thermotaxis.

This consists of afferent neurons with special terminations in the skin which are sensitive to temperature, efferent neurons activating various mechanisms whereby heat loss or heat production is varied and a central coördinating machinery. The afferent nerves subserving temperature sensations enter the cord by the posterior roots and, after crossing, ascend in the antero-lateral columns. They have been traced to the posterior part of the optic thalami. The efferent nerves concerned in modifying heat loss are the nerves to the vessels of the skin, to the sweat glands, and to the erector muscles of the hairs. The outflow of nerve-fibres from the cord to the sweat glands and *arrectores pilorum* closely follows the sympathetic distribution of the vasomotor nerves to the skin. The nerve paths along which impulses pass which modify heat production are extensive, and include the nerve-supply to the musculature and all the active tissues of the body, including the endocrine glands.

That heat production in muscles is under nervous control otherwise than through the motor nerves is held by Mansfield and Lukàcs (1915), because they found that in curarised animals section of motor nerves caused a fall in oxygen consumption. Fr and Jansson (1923) also concluded, from experiments on animals in which the motor n were cut and the oxygen consumption of the mu of the leg was measured on both sides and on one the arteries were stripped of nerve-fibrils, sympathetic fibres control heat production voluntary muscle. Newton (1924), however, find no evidence for this conclusion. Man and Lukàcs and Freund and Jansson take granted that a separate sympathetic innervatio voluntary muscle has been established anato ally, but this, too, is now by no means gene accepted.

The situation of the central coördinating mecha has been approximately defined in some of the l animals by removing or severing successive por of the central nervous system from below upw and from above downwards, supplemented destroying limited areas of the brain and subsequ observing to what extent and in what manner the taxis was impaired. Many such experiments been vitiated by anæsthetics or complicated by s or irritation, and it is only from those in which animal had completely recovered from the opera at the time the observations were made conclusions can be safely drawn. The early obse tions of Pfluger (1878) on the condition of a dog

FIG. 1.



Influence of sojourn at an air temperature of 3° C. on the temperature of normal bitch and bitches with sectio the cord at different levels made some months previo Sherrington (1924).

section of the cord at the sixth cervical verte and many observations on man after lesions in region indicated that coördination was performed some portion of the nervous system above this le Kennaway and Pembrey (1912) studied the ther tactic ability and the respiratory exchange in r and rabbits before and after severing the cord below the brachial plexus. The section obliter the regulation of heat loss from the paralysed port but a considerable amount of control over l production remained. The animals' consump of oxygen was increased in their efforts to compen

r the greater loss of heat, and the authors assume at all this increased combustion was accomplished muscles of the portion of the body anterior to the tion.

More precise information of the effect of section the cord at different levels upon the ability of an imal to control its temperature has been afforded the experiments of Freund and Strassmann (1912) d Freund and Grafe (1912) on rabbits, d those of Sherrington (1924) upon gs.

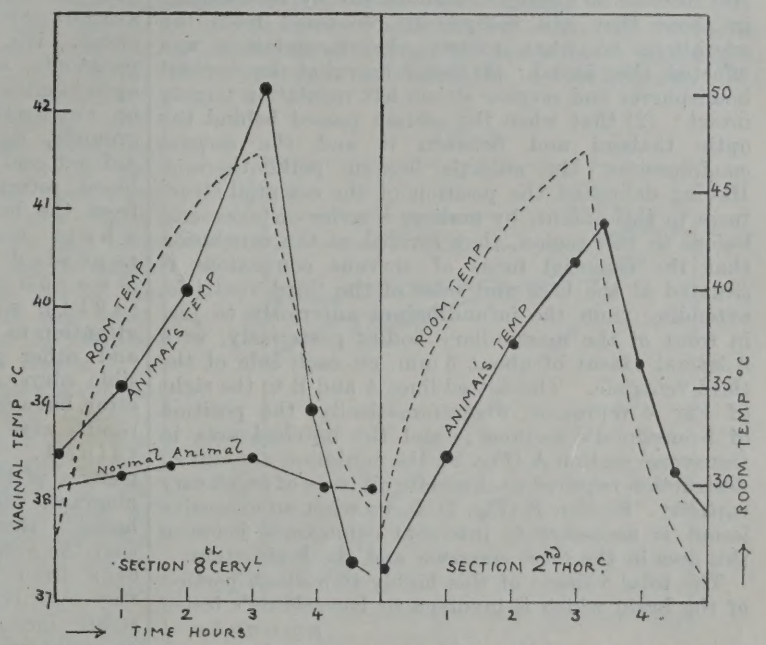
Sherrington's experiments are particularly convincing, as he had at his disposal animals in which spinal sections had been made from one month to one and a half years previously. The dogs were in good health but had to be kept in a room at 26° C. in order to maintain a body temperature of 37° C. Figs. 1 and 2 illustrate the effect of sections of the cord at different levels upon the animals' power to accommodate when their surroundings were cooled or heated. Observations upon normal dogs are included for comparison. The normal dog, when the temperature of the air was 2° C., coiled himself up to reduce his surface, roughened his coat to improve his insulation, diverted his blood flow from the surface, until his nose and extremities were cold to the touch, and shivered occasionally to increase his heat production; by these means he maintained his body temperature. The paraplegic dogs could only do all these things over a proportion of their body, diminishing as the level of the cord-section was higher. They were progressively handicapped by the greater extent of their paraplegic and poikilothermic portion, and their body temperature fell more or less rapidly. Gardiner and Pembrey (1911) have collected an interesting series of cases of traumatic section of the cord in man which illustrate the same fact.

In some further experiments Sherrington established that both shivering and the erection of hairs require a præspinal nervous apparatus, and that this can be stimulated by lowering the temperature of the blood, even when the remaining sentient surface of the skin is above the usual temperature. The converse holds for sweating, which occurs on stimulation of præspinal centres even when the surface is cold. This does not imply that either sweating or shivering are only produced by changing the temperature of the blood.

Sherrington's experiments did not include observations on the respiratory exchange and, apart from the termination of shivering, afford no information as to how far nervous control of production is handicapped by spinal section. This was done by Kennaway and Pembrey (1912), and has more recently been the subject of experiments by Freund and Grafe (1912). They agree with Pembrey and Kennaway that, in the rabbit, dorsal section by no means eliminates chemical regulation. They found that afterwards the rabbit consumes 30 per cent. more oxygen than before at the same temperature. This must be so if it is to maintain the same body temperature, for the heat loss from the paraplegic portion cannot be controlled.

The interest of their results resides in the discovery that if the section be made at the seventh cervical instead of at the second dorsal, or if after section at the second dorsal the cervical nerves are severed or the stellate ganglion removed, the animal behaves almost like a poikilothermic creature. By either of these procedures they will nearly have eliminated physical regulation from the whole of the body, but this does not account for their finding that afterwards the animal is not able to increase heat production, for the extra amount of musculature eliminated is not great. They are of opinion that between the level of the seventh cervical and second dorsal segments nerve-fibres emerge which pass into the sympathetic and are distributed to the liver and other glandular organs. That the thyroid was one such was an obvious inference, but they discard this interpretation as they found no further impairment of chemical regulation in a dog with dorsal section after thyroidectomy.

FIG. 2.



Effect of raising temperature of room from 26° to 46° C. on normal dog and bitches with section of the cord at eighth cervical or second thoracic level. Sherrington (1924).

Later Freund (1914), and also Plaut (1922), dissected away the nerves from the hepatic artery in dogs in which a dorsal section had been made. By this procedure the animals' capacity to increase heat production when cooled was further impaired, and they conclude that the suggested outflow into the sympathetic between the lower cervical and upper dorsal finds its way to the liver either with the vagus or along the vessels. This would indicate an unexpected origin and course, and the whole matter is far from clear.

Freund and Janssen's (1923) recent conclusions that nerve-fibres which leave the cord in the cervical region, join the sympathetic chain, and ultimately find their way along the artery to the muscles of the hind leg and control the combustion in these muscles, independently of the motor nerves, is difficult to accept. The experimental procedures upon which this "proof" was founded were very difficult and the protocols indicate that the errors of observation were great.

LOCATION OF A THERMOTACTIC "CENTRE" BY SUCCESSIVE ABLATIONS OF THE ANTERIOR END OF THE CENTRAL NERVOUS SYSTEM.

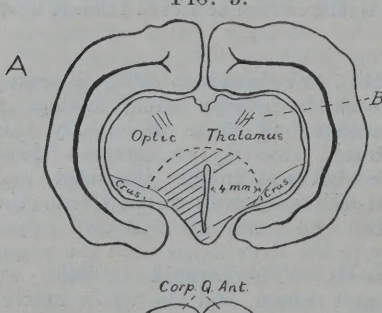
Goltz's famous dog, from which he removed the cerebral hemispheres and a good part of the *corpora striata* and optic thalami, lived 18 months and regulated its temperature. On the other hand, the usual method of decerebrating a dog or cat by passing a spatula along the tentorium to the base of the skull obliterates all trace of regulation. A decerebrate cat has been kept alive for five months by de Barenne (1919)

and one month by Bazett and Penfield (1922). These remnants of animals were poikilothermic and had to be kept in a room about 30° C. to maintain a body temperature of 40°. These observations limit the position of the central coördinating mechanism anteriorly to the region of the interbrain.

More precise localisation in the rabbit has been achieved by Isenschmid and his colleagues Krehl and Schnitzler (1912, 1914) (Figs 3, 4). By ablations and sections on a series of animals and by ascertaining in those that had completely recovered from the operations to what extent thermoregulation was affected, they found: (1) that removal of the cerebral hemispheres and *corpora striata* left regulation largely intact; (2) that when the section passed behind the optic thalami and between it and the *corpora quadragemina* the animals became poikilothermic. Having delimited the position of the essential structures to this extent, by making a series of transverse lesions in this region, they arrived at the conclusion that the essential focus of nervous connexions is situated at the base and sides of the third ventricle, extending from the infundibulum anteriorly to just in front of the mammillary bodies posteriorly, with a lateral extent of about 3 mm. on each side of the third ventricle. The dotted lines A and B to the right of Fig. 4 represent, diagrammatically, the position of Isenschmid's sections; and the hatched area in transverse section A (Fig. 3), the minimum amount of destruction required to eliminate all trace of regulatory capacity. Section B (Fig. 3) shows what an extensive lesion is necessary to intercept connexions between this area in the *tuber cinereum* and the brain stem.

The total volume of this highly important portion of the brain which is involved in Isenschmid's lesion amounts, I reckon, to about 0·1 c.cm. It is a region which has been shown by Hasama (1929) to be in connexion indirectly with several sympathetic outflows—e.g., vasomotor, pilomotor, pupilodilator, cardiac augmentors, and sweat glands. The afferent connexions of this nervous exchange are multitudinous. It is in connexion, through the optic thalami, with the nerves of temperature sense from the whole surface of the body and with many other sensory nerves too, for pain and cayenne pepper produce sweating. Also it must have connexions with the higher centres, for Gessler and Hansen (1927) find that in a hypnotised person the suggestion of coldness may produce vasocontraction in the skin, goose-flesh and shivering in a warm room, and that the suggestion that the patient will not feel cold may inhibit these manifestations when the rate of heat loss is sufficient to occasion a fall in body temperature.

FIG. 3.



Section just behind infundibulum in the rabbit. Hatched area is that required to abolish thermoregulation. (Isenschmid and Schnitzler: Arch. f. Exp. Path., 1914, lxxvi., 202.) B is 4 mm. below section A ventrally and 8 mm. below section A dorsally. Destruction of hatched area did not greatly impair thermoregulation. B.V.A. = Bundle of Vicq d'Azyr.

SENSITIVITY OF DIFFERENT PORTIONS OF THE THERMOTACTIC NERVOUS APPARATUS TO TEMPERATURE.

The peripheral endings of the nerves of temperature sense are not the only part of the nervous system which is sensitive to temperature. Kahn (191[illegible]) showed that warming the blood-supply to the brain by surrounding the carotid artery of a dog with a jacket of warm water produced acceleration of the heart-beat, dilatation of the peripheral vessels, and secretion of sweat. His experiments were open to criticism on technical grounds, as he did not cool the blood returning from the brain. They were repeated by Moorhouse (1911), with attention to this and other possible sources of error, but similar results were obtained. By using a plethysmograph Moorhouse showed that the volume of a limb was very sensitive to small increases in temperature of the blood supplying the brain, and that these increases were observed before the augmentor action on the heart.

FIG. 4.

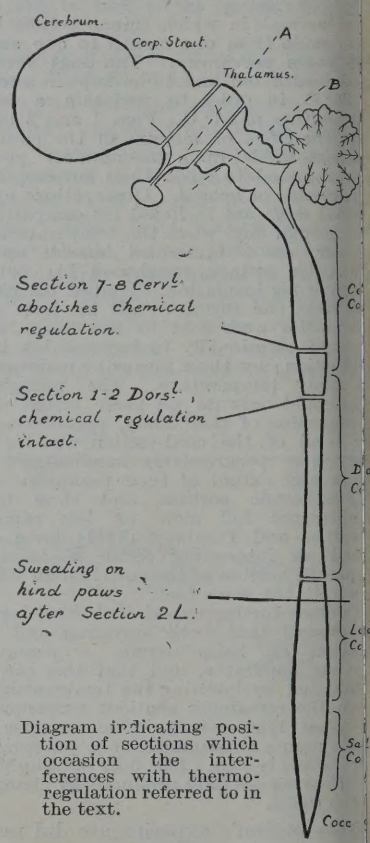


Diagram indicating position of sections which occasion the interferences with thermoregulation referred to in the text.

That the thermotactic apparatus at the base of the brain is sensitive to temperature and responds so as to regulate both heat production and heat loss was most satisfactorily demonstrated by Barbour (191[illegible]) who introduced a double cannula through a trephine opening in the skull of a rabbit down to the base of the lateral ventricle. The operation was performed aseptically and, by an ingenious technique, the cannula could be left in situ and the animal allowed to recover from the anæsthetic and the initial disturbance. When cold water was circulated through the cannula, vasoconstriction of the vessels of the ear was obvious, the oxygen consumption increased (Barbour and Prince (1914), and shivering occurred although the body temperature of the animal was above normal. On the other hand, the circulation of water a few degrees above that of the body gave rise to flushing of the skin and diminished the oxygen consumption.

The significance of Barbour's experiments has been belittled because he found it necessary to use water 5° C. above or below the temperature of the brain in order to produce the effects. That criticism appears to me unjust. The end of his double cannula was only somewhere in the neighbourhood of the sensitive nerve-cells of the thermotactic centre subsequent

limited by Isenschmid, and generally in the lateral ntricle. It was surrounded by brain tissue through ıich blood was circulating. In 1914 I repeated ırbour's experiments, but not always successfully. obviously did not always hit the right spot. I ınd that his double cannula destroyed too much ain tissue, and I was more successful with a fine ıstic catheter with a solid silver tip enclosing a ıe metal inflow tube about 1 mm. bore. In the llowing year Hashimoto (1915) also repeated ırbour's experiments, but used a double cannula both sides of the brain. Under these conditions was not required to employ water so hot or so cold Barbour found necessary to obtain his effects. ith this bilateral arrangement Hashimoto could ol one side and heat the other, and then sometimes oduced constriction of the vessels in one ear and latation in the other. Barbour's observations were nfirmed for the cat by Prince and Hahn (1918). y placing a hind leg in a plethysmograph they were ıle to show that the volume of the leg increased diminished according to whether the base of the ain was heated or cooled. This did not occur ter removal of the skin, indicating that the vascular sponse was confined to the superficial vessels.

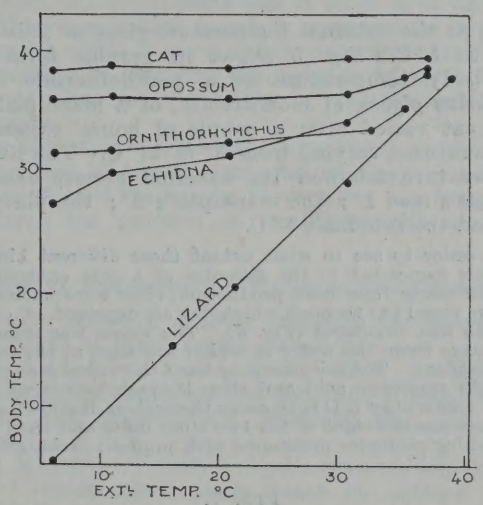
So far I have emphasised the proofs that the central echanism of thermoregulation is itself sensitive temperature, and so organised that it discharges pulses through appropriate nerve channels accordg to whether its temperature rises above or falls low a predetermined level. The mechanism is, wever, more elaborate than this. Instead of waiting r the blood temperature to rise or fall, and meanıile wasting calories, adjustment can be brought out reflexly from the surface. The centre is in nnexion with the nerves of temperature sense from e skin, and responds with rapidity by efferent ıpulses which modify heat loss from the surface or, aybe, by others which result in an increased or minished production of heat. It has been suggested at such coördinated reflexes could themselves hieve homœothermism, and the importance of the ct that the central nervous machinery is also directly nsitive to temperature is minimised by some ıysiologists. Consideration will, however, show that rect sensitivity of the centre is essential. A reflex echanism to diminish heat loss and increase produc-n when the skin cools would work progressively ıd the temperature inside would rise. In fact, rigor would occur. The reverse would happen if ısodilatation in the skin occurred in response to armth. The skin would become progressively armer and the body temperature fall.

There must be some mechanism to control these flexes as soon as they have accomplished their ırpose, and I suggest that it is the direct influence the slightly warmed or cooled blood reducing the nsitivity of the appropriate parts of the central paratus to stimulation by impulses arriving by one th or another.

The conception of the central nervous mechanism r thermoregulation which best interprets physiogical, pathological, and pharmacological observations d experiments is a slight elaboration of one put rth by Hans Meyer (1913). Meyer regards the ermotactic nervous apparatus in the *tuber cinereum* be composed of two coupled nerve centres alogous to the inspiratory and expiratory centres r respiration. One of these he calls the thermogenic, e other the thermolytic centre. Each is sensitive appropriate, direct, and reflex stimulation, their fferent connexions being such that antagonistic sults follow. Meyer supposes that stimuli activating the thermolytic centre at the same time inhibit the thermogenic, and vice versa. The thermogenic centre must, however, be associated with yet a third collection of nerve-cells, impulses emanating from which occasion a sparing of heat loss by constricting superficial vessels and erecting hairs, for the first and sometimes the only response to impulses along nerves from " cold spots " on the skin is to economise heat loss in this way. For this piece of nervous apparatus I suggest the term thermopheidic centre ($\phi\epsilon\iota\delta\omega$ = thrift).

In this survey I have not yet exhausted the means available to an animal for temperature adaptation. Both thyroxin and adrenalin are calorigenic. The

FIG. 5.



Variation of body temperature of different types of animals by sojourn for two hours in an environment of 5° to 35° C.

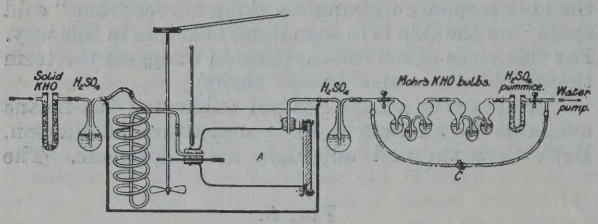
former is slow in action but the effect is prolonged. W. Cramer (1916, 1918, and 1919) has demonstrated by his histochemical method that both the suprarenals and the thyroid are stimulated by cold to excessive activity. This has been confirmed for the former by the Hartmans (1923) and more recently by the convincing experiments of Cannon and Querido (1924), and for the latter by Mills (1918) and Hart (1922) from histological changes in the gland. Boldyreff (1913) showed that a dog after thyroidectomy, was handicapped in protecting itself against cold, and the same disability was demonstrated by Kovenchewsky (1926) in rabbits. The importance of this indirect humoral method of regulating heat-production is championed by Cramer (1916), Meyer (1920), Aub, Forman, and Bright (1922), and Cannon (1925).

History of Homœothermy.

It may be safely assumed that the present perfection of thermal adjustment possessed by the higher mammals was acquired gradually, but most of the types of animals which may have possessed the faculty in a rudimentary form have disappeared from the face of the earth. There are, however, in Australia two interesting creatures with many characteristics intermediate between mammals and reptiles. I refer to the monotremes, which have a cloaca, lay eggs, and suckle their young. It seemed to me that an examination of their thermotactic capabilities might be interesting, and when in Melbourne I made some experiments with this object (Martin 1902). Both the monotremes have temperatures considerably lower than mammals. The duck-billed platy

Ornithorynchus paradoxus, maintains a fairly constant temperature provided it is not too hard put to do it, but the ant-eater, *Echidnia hystrix*, is really intermediary; its temperature varies 10° C. (18° F.) or

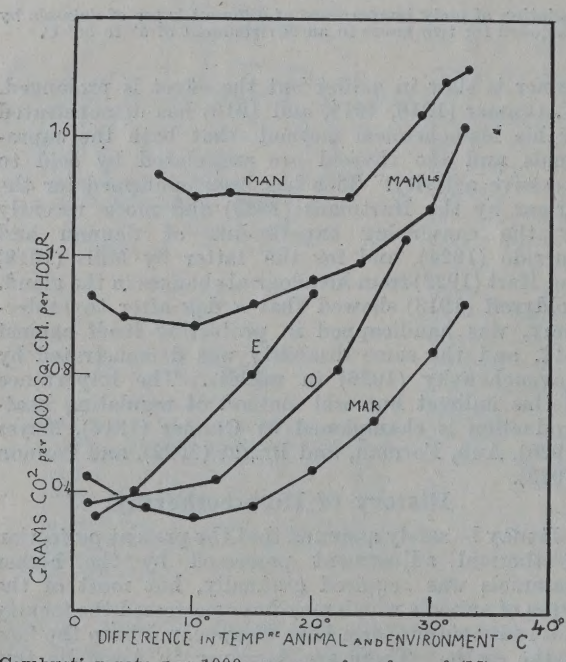
FIG. 6.



more as the external temperature rises or falls from 30° to 5° C. Fig. 5 shows in graphic form how the body temperature of a poikilothermic lizard (*Cyclodus gigas*), of monotremes, of a marsupial and of a cat varied after a couple of hours' sojourn at temperatures varying from 5° to 37° C. The lizard's temperature followed the external almost exactly; the cat's rose 1°; the marsupial's 2°; the platypus' 4°, and the echidna's 8° C.

In order to see to what extent these different kinds of animals responded to the stimulus of a cold environment by increasing their heat production, they were enclosed in a glass vessel (A) through which dry air deprived of carbon dioxide was circulated (Fig. 6). The vessel was immersed in a large bath, the water in which was kept at the desired temperature. The air emerging from the vessel was passed through sulphuric acid and then through two large Mohr bulbs containing K O H to catch the carbon dioxide formed. The increase in weight of the two Mohr bulbs and the U tube containing pummice moistened with sulphuric acid, afforded

FIG. 7.



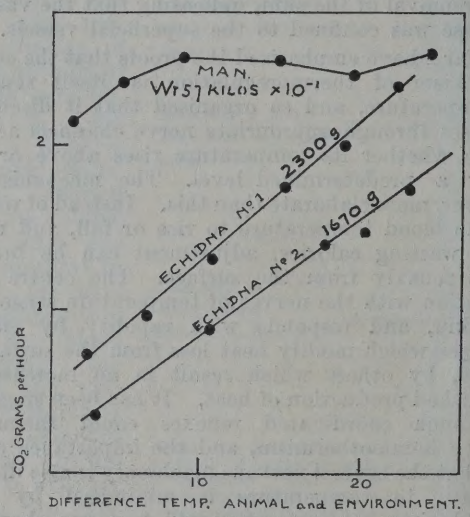
Combustion-rate per 1000 sq. cm. of surface of (M) mammals (cat and rabbit), (E) echidnas, (O) ornithorynchus, and (MAR) marsupials, according to the difference in temperature between them and their environment. The graphs represent the average results of several experiments. The observations on man were made by Voit (1878).

a measure of the carbon dioxide formed by the animal during the period.

Fig. 7 shows graphically the variation in combustion in the animals according to the difference in temperature between them and their surroundi together with that of a clothed man, observed Voit (1878) under somewhat similar conditions. rate of combustion is expressed in grammes of carl dioxide per hour per 1000 sq. cm. of surface. T is done because the animals were of different si and in the same kind of animal of the same combustion varies nearly in proportion to its surfa

The cost in fuel of the various animals for the sa external temperature varies. This is partly accoun for by their insulation, partly inherent in them. I particularly noticeable at higher external temperatu when man is expending five times as much energy a marsupial, wastefully and to his discomfort. contrast to all the other creatures, it was not u the external temperature fell below 14° C. t Voit's man varied his heat production at all. T echidna evidently utilises chemical regulation m (without, however, achieving a constant temperatu then the marsupials, and the cat and rabbit le until the external temperature falls below 10°

FIG. 8.



Combustion-rate of the monotreme *Echidna hystrix* compa with that of man according to rate of heat loss. The obser tions on man were made by Wolpert (1898).

The curves are composite ones for several anim of the same kind. Fig. 8 illustrates the carb dioxide production of two echidnas and a man plott against difference in temperature between inside animal and environment. The ordinate for the m is divided by 10. The combustion in the echidna within the error of such an experiment, proportion to this difference, whereas the combustion for the m is largely independent of it. The echidna has sweat glands. It does not pant when it gets h although it shivers violently with cold. As it do not seem to have means of varying the wat evaporated, if its combustion is proportional difference in temperature between it and its enviro ment, it is varying production closely in proporti to loss, a fact which suggests that this is the on means of adjustment employed.

Regulation of temperature by varying producti would seem, therefore, to have been the first meth arrived at in the development of homœothermis It is the cheapest, but is no protection against hi air-temperatures. At an external temperature 35° C. an echidna soon succumbs. A boc temperature of 39–40° is incompatible with lif In their natural conditions echidnas burrow, and

ɔt weather emerge only after sundown. In the winter ey hibernate, and reduce the expense of existence a minimum.

If chemical regulation is phylogenetically the more ıcient method it should, in accordance with bio-gical principles, precede regulation by varying loss the development of the young animals. Pembrey 894) studied the power of adjustment to temperature ɔssessed by the embryo chick in the egg and that the chick after emergence. He found that up to e eighteenth day a chick in the egg behaved like cold-blooded creature, and that its carbon dioxide oduction rose and fell with the temperature of its rroundings. At the nineteenth and twentieth day began to do the opposite, and before leaving the ell had already acquired a considerable capacity to ry heat production in response to external tem-rature. One day after hatching, a chick was found double its carbon dioxide production when its vironmental temperature fell 20°. Pembrey (1895) so made similar observations on mammals which e born in different states of immaturity. He und that they all possessed some power of regulating at production, varying according to the stage of velopment they had attained when they commenced eir extra-uterine existence. As he did not make rect calorimetric observations, Pembrey's experi-nts do not decide when physical regulation first pears. This has, however, been done by Babak 902) on new-born babies. From his observations concludes that physical regulation is not yet anifested at birth, but is gradually developed a few ys afterwards.

A REVIEW OF THE TREATMENT OF ASTHMA.

r W. R. F. COLLIS, M.D., M.R.C.P. LOND., D.P.H.,
SEARCH FELLOW AND ASSISTANT PATHOLOGIST, THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON.

THIS paper is based upon the study of the treat-ent of some 60 children, with asthma of all types. ɔ disease can show a more diverse and baffling erature and to the casual observer the differing atements of the various camps must seem almost licrous.

In a recent paper, however, McDowall [1] has shown at all may be partly right. Assuming that bronchial nstriction is the main symptom of asthma, he mmarises the various methods by which this may brought about —viz.: (1) *Directly*, by the inhalation irritating gases. (2) *Chemically*, by histamine d peptone. (Here he describes a biphasic reaction the part of the bronchi to these substances, the st being an immediate contraction, the latter a layed and much more profound relaxation.) *Nervously*, through the vagus. (The vagus may stimulated psychically by suggestion or reflexly rough the fifth nerve by irritation of the mucous mbrane of the nose.) McDowall quotes some portant experiments of his own which show that reign proteins have a profound influence on the gal system. The injection of foreign proteins ɔ certain animals tends to hypersensitise their gal systems and in certain cases leads directly to ɔnchial constriction.

If we examine the different treatments of asthma this light it is possible to see that one and all, under tain circumstances, can be of theoretical value. ptone, administered intravenously, between attacks small enough doses will fail to give its primary reaction of constriction and only give its more powerful secondary reaction of relaxation. Psychotherapy will remove any psychical stimuli which may "start off" a hypersensitive vagal system. Operation on the nose, in cases of nasal defect, will remove the local reflex through the fifth nerve to the vagi. Hydrochloric acid and pepsin, by aiding digestion, particularly in cases of achlorhydria or hypochlor-hydria, will prevent the absorption of the allergising protein molecules into the blood stream. Specific elimination of offending proteins will remove the patient from contact with the allergising substance, and desensitisation, by repeated injections of minute quantities of the allergen, will produce a temporary circulating antibody. The action of glucose is not clear, but Oriel claims that it tends to steady the unstable metabolism found in a particular type of asthmatic child. X ray therapy and protein shock act presumably by changing the body chemistry tempor-arily in some way, possibly by the production of histamine.

By accepting McDowall's hypothesis as the true explanation of the fundamental ætiology of asthma we can discard the narrow view of any one camp and approach the problem of treatment with an open mind.

Logical Sequence of Various Treatments.

It now becomes possible to group the recognised treatments in their logical sequence :—

(*a*) *General measures.*—Under this heading is included the general care of the child's health, both mental and physical—e.g., sufficient rest, diet, and exercise.

(*b*) *Measures to remedy faulty digestion and metabolism.* Bray [2] holds that many cases of asthma have a reduction or absence of hydrochloric acid. In these cases he claims that great benefit may be obtained by giving a mixture of hydrochloric acid and pepsin. Oriel [3] describes a type of asthmatic child in which the asthma is associated with other allergic conditions, such as eczema and cyclic vomiting, and in which the blood chemistry shows a high amino-acid content and a low blood-sugar. These cases, he states, show an unstable metabolism alterna-ting between an acidosis and an alkalosis. He claims that glucose given in large quantities (four ounces per day) will help to steady the metabolism of the child and cause cessation of attacks.

It is clear, therefore, that a careful study of the child's body chemistry should be made in all cases, and where conditions as described by Bray and Oriel exist their treatment should be adopted. In some patients these types will no doubt overlap, in which case a combination of glucose and hydrochloric acid may well be tried.

(*c*) *Measures to rectify nasal defects.*—A skilled rhinologist who has made a special study of asthma should examine all cases. He will be able to select a number where a deviated septum, hypertrophic rhinitis, or sinus infection is the causal factor and which can be cured by operative procedure. The diagnosis of cases due to infection of the upper respiratory passages is more fully discussed below.

(*d*) *Psychotherapy.*—In children it is very rare for the primary cause of asthma to be a neurosis, the curing of which leads to cessation of attacks. I know of three patients cured by psychotherapy, but they were all women between 40 and 50 years of age. However, we must include the breaking of the "habit" of asthma under this heading. It is essential to treat the attacks efficiently so as to dispel fear from the child's mind, and to continue

investigation until we find some method of treatment which will lead to cessation of attacks, if only for a while, as auto-suggestion plays a very big part in the causation and confidence in eventual cure is essential.

(*e*) *Specific diagnosis of allergic type.*—This is best accomplished by a comparative study of the physical examination with a special history and a subsequent number of skin tests. Large numbers of skin tests by themselves are of little value and are often misleading. This method has been much abused in the past, unfortunate patients having been subjugated to over 100 such tests by the "specialist" without any clear rationale.

By these means the allergic type may be divided into main sub-types depending on the kind of allergen to which the patient is hypersensitive and its mode of entry into the body—e.g., respiratory and alimentary other than bacterial, and bacterial products from foci of infection. The sub-types may be yet further sub-divided according to the actual allergen or allergens involved. The Table shows some 33 cases

Table of Types.

worked out on these lines. They were all tested with extracts made up in the hospital laboratory; previously, extracts supplied by two well-known firms had been used with only very partial success. All the cases included were studied for over 12 months, and although the Table is far from perfect it serves to demonstrate a number of important points.

In this Table all the bacterial cases are from the respiratory passages, for I was unable to demonstrate intestinal infection as the causal factor in any of my cases. The respiratory group is divided into three sub-groups—viz., epidermal, pollen, and dust (the dust referred to was obtained from sweepings from the patient's own houses). Only one case was demonstrated to be hypersensitive to one food, and one only, and hence most of these cases fall into the multiple group.

For the sake of simplicity, only a limited number of skin tests have been included. Skin reactions to bacteria are brought about by a different mechan than that of the other protein cutaneous reactio the former occur at once and are probably a nerv reflex, while the latter do not reach their maxim for 24 hours, being of serological origin, and he have been excluded from this Table.

If the Table is studied the frequencies will be s to fall into definite positions in the different gro showing a correlation between history, phys examination, and cutaneous reactions. For exam most of the bacterial cases occur in winter, associated with chronic infection, and give gener negative skin reactions, while the pollen type oc in summer and shows a marked skin hypersensiti to pollen.

TREATMENT AFTER DIFFERENTIAL DIAGNOSIS.

The first five sub-groups should be treated specific desensitisation and elimination. For succ ful treatment of bacterial cases the closest coöperat between the nose and throat surgeon and the physic is essential. It is not sufficient to hand over th cases to the former with the tentative diagnosis "infection," for it often impossible for the surg to tell which is primary in cases of nasal de associated with asthma. In the cases operated u the morbid remains or washings should be set as and cultured; from these cultures vaccines sho be prepared by growing the organism in broth 24 hours and then killing it by heat and carbolis it. By these means the exotoxins are retained well as the endotoxins. Subsequently the pati should be treated by injections of minute doses of diluted whole broth culture. All the bacterial ca in my Table were treated in this way; three cea having attacks altogether, in one the attacks ten to recur after eight months, two were much improv while one remained unchanged.

The epidermal, pollen, dust, and food sub-gro should be treated by elimination, and desensitisat by inoculation at weekly intervals with minute do of the offending antigen. As in the case of hay-fe it will be found that the immunity thus procu is but temporary, and tends to pass off in from to eight months after the course of treatme About half my cases showed this tendency. second and if necessary a third course of "desensit tion" should be tried in these cases. This type asthma is analogous with hay-fever. In the latte has been found almost impossible to desensitis patient in the presence of the antigen. It is which makes the treatment of asthma by desensit tion so difficult, as it is often impossible to rem the patient from contact with the offending prot (antigen) while desensitisation is in progress.

It is doubtful if we are actually desensitising patient by this means. In hay-fever and asthma skin reactions often remain positive during treatm although they may vary in intensity. It is, therefo more probable that we are merely producing a te porary antibody in the blood, and that when this g used up the attacks tend to recur once more, the fore protein being able again to reach the hypersensit cells. Weil[4] has shown, in experiments on guinea-p with anaphylaxis, that the anaphylactic state m be masked temporarily by the injection of sm amounts of the antigen producing a temporary hom logous antibody. In this connexion it is interest to note a possibly analogous condition with bacterial allergy described by Swift and co-worke They have shown that bacterial allergy is not altoget specific and that groups of organisms produce a gro allergen. Dochez [6] describes both specific and n

ecific allergens from bacteria. In cases of multiple persensitivity it has often been observed that sensitisation to one allergen will cause cessation attacks, even when the patient is exposed to her allergens to which he is still sensitive. The ccess of W. S. van Leeuwen's tuberculin treatment n thus be explained. Tuberculin is a very powerful ergen, and when given in minute doses—e.g., rting with 0·1 c.cm. of one millionth O.T.—it is rely such a method of desensitisation.

The multiple sub-group in this Table comprises per cent. of the total. Actually in England, ere pollen asthma is rare in children, it would be least 50 per cent. It is difficult to say what actual rcentage of all cases attending an asthma clinic London would fall into this sub-group, but I uld venture to say that they would be at least per cent. It is clear that cases cured by more neral measures, already referred to, although they ay have been multisensitive, are not now included this sub-group. It is the problem of what to do th this multisensitive type of case, often indeed e most severe, which has taxed the asthma specialist the past, and it is here, I think, that non-specific erapy has a place. Of 14 cases treated by non-ecific therapy of which I have full notes, 3 ceased ving attacks altogether, 2 tended to recur after ght months, 3 were much improved, and 6 were improved. In the literature all forms of non-ecific treatment have adherents. Non-specific sensitisation to tuberculin or some other allergen easily carried out. X ray therapy, where possible, slightly more efficacious; either of these treatments ay well be tried. Peptone and like compounds are t advisable, as they may lead to dangerous results very hypersensitive cases. Protein shock tends lead to deterioration of the child's general health d is not to be recommended, except as a last resort.

Although discussion of palliative measures is not rt of this paper, control of the actual attack is of ch fundamental importance in the treatment of the ole condition that it is necessary to mention it. this connexion two drugs, adrenalin and ephedrine, th strong sympathetic stimulants, must be primarily nsidered. Adrenalin will cut short the attack at ce if given in large enough doses hypodermically. no case should more than ℥3 be given in the first ace to a child, but if this does not produce the sired effect another ℥3 may be given at the end of minutes, and so on until the worst of the spasm is ieved. Ephedrine has the advantage that it may given by mouth or in the form of a nasal spray, d hence can be used by the patient without call on the doctor or nurse; 0·025 g. of ephedrine lphate may be given with safety by mouth, or a per cent. solution of the chloride as a spray. The ter is of particular value in cases of pollen asthma d those associated with nasal defect. I have used is drug in over 50 cases with excellent results and ve not found it upsetting to the child. This ay have been due to the fact that we were using a ecially pure preparation sent us from the pharma-logical department of the University of Peking. ay and others have not reported equally successful sults from the preparations commonly used in is country.

There are many time-honoured methods of treating e attack, chiefly by inhalation of compounds ntaining stramonium or lobelia, but none compare efficiency with adrenalin or ephedrine.

It is possible, then, to provide the patient with such effective defence against the acute spasm of asthma at fear of the attack may be largely overcome, a factor of the greatest psychological importance in the general treatment of the disease.

The work referred to in this paper was done while holding a Rockefeller Research Fellowship. I wish to thank Dr. E. A. Park for allowing me to use cases from the Children's Department of the Johns Hopkins Hospital, and Dr. L. H. Gay for his help and advice.

PRURITUS ANI ET VULVÆ.*

BY L. F. R. KNUTHSEN, O.B.E., M.D. EDIN.,
AND
F. HOWARD HUMPHRIS, M.D. BRUX., F.R.C.P. EDIN., D.M.R.E. CANTAB.

THE causes of pruritus ani et vulvæ are many and varied. Some of these, such as eczema and certain dermatoses, are obvious upon inspection, or, at any rate, become so after a comparatively simple examination, while the dependence of the distressing condition upon constitutional reasons, such as diabetes, the gouty diathesis, and changes in adjacent structures, including piles and enlarged prostate, are well known. Other contributory factors may be the climacteric period, colitis, constipation, certain articles of food, oxyuris, pediculi, and, of course, affections of the rectum or vagina. Pruritus, which has an underlying bacterial origin, be it *Bacillus coli*, *Streptococcus fæcalis*, or *Staphylococcus albus*, is familiar, and a mycotic variety, due to epidermophyton and trichophyton, can sometimes be demonstrated by careful and repeated microscopic examinations.

There is, therefore, a great variety in the known ætiology, but the pruritic condition is often met in which diligent examination fails to find a cause. These cases are attributed to disease of the nerves or interepithelial nerve-fibrils supplying the affected areas. Many cases without any discoverable ætiological factor will become intelligible when laboratory methods have advanced. Already it is a reasonable belief that there is no such thing as pruritus sui generis.

Symptomatology.

The symptomatology of pruritus may be epitomised with the one word "itching"; all the signs and symptoms can be traced to the violent scratching to which a patient resorts in order to find relief. The itching is usually paroxysmal, as a rule worse at night when the patient is warm in bed, and in the early morning owing to secretion of mucus. The disease is more common in men than in women, and being a more frequent affection of the well-fed and well-to-do, is oftener seen in private than in hospital practice. The excoriations, the little cracks and fissures, the ulcerative and pustular lesions, indurations, and eczematous appearances are all due to this cause; local mischief may be originally due to any of the reasons set out, but is then exaggerated by the scratching. The itching is often of a severe type, and may lead to far-reaching irritation and to the more serious consequences of insomnia and

* Read on August 6th before the Eighth International Congress of Dermatology and Syphilology at Copenhagen.

melancholia; even insanity and suicide, though remote probabilities, have to be borne in mind, as well as the possibility that we are dealing with a prodromal symptom of malignant disease. Fearful of the onset of a paroxysm the sufferer withdraws from his or her fellows. Irritability and loss of temper on trifling occasions are common, and these patients are apt to become morbid and morose, even though there are no more serious mental manifestations. In pruritus of mycotic origin there may be seen minute red, slightly raised, infiltrated patches in the peri-anal region, occasionally arranged into two curved lines.

The pruritic area is reddened, and the fissures and cracks are usually small and moist. When they affect the area of skin surrounding the anus, puckered up by the action of the corrugator cutis ani, they can only be seen when the skin is put upon the stretch. Not only the peri-anal skin may be affected, but the irritation may extend to the scrotal area and also up the abdomen.

All the symptoms have been much observed and recorded, and their recapitulation must be excused because all have to be watched for in the treatment of this obstinate malady.

Treatment.

The successful treatment of pruritus taxes therapeutic ingenuity, and the reason for so many failures, partial or total, is that the attention to detail—without which success is often impossible—proves tedious both to patient and physician alike. But most patients will willingly submit to prolonged temporary inconvenience when accompanied with improvement, however slow, rather than have recourse to surgical interference—Ball's operation being the recognised operation.

Consider the local complications which it may be necessary to treat. Among these are chronic constipation, hæmorrhoids, ulcers, enlarged prostate, discharges (including irritant urine or fæces or even leakage of petroleum), caruncles, persistent Pacinnian bodies, hypertrophied anal papillæ, and any co-existent skin diseases, such as eczema. Of course, attention must be paid to the general health of the patient. It is sometimes found that in his diet there is something, perhaps a favourite food, towards which he is showing an evil idiosyncrasy. Moderation in alcohol and tobacco will be found beneficial. Especially, every effort should be made to restore sleep when insomnia is present. Luminal is useful, and it should be remembered that opium and its derivatives often not only fail to give relief but actually aggravate the irritation. Direct treatment falls under the two groups comprised in physiotherapy.

The small cracks which are of so frequent occurrence may be treated by means of ultra-violet radiation and X ray, but they may also be healed by painting them with friar's balsam or touching them lightly with a stick of silver nitrate. The treatment *must* persist until the most careful examination fails to reveal any trace of erosion. Those which are associated with pruritus of mycotic origin are more amenable to collosol iodine oil or tr. iodi (half strength), or mitigal, an organic sulphur preparation (Schottmuller), or some such prescription as Deek's ointment half strength.

The formula for Deek's ointment is:—

℞	Salicylic acid	4 parts
	Bismuth subnitrate	10 ,,
	Mercury salicylate	4 ,,
	Oil of eucalyptus	4 ,,

Vaselin and lanolin equal parts up to 100 parts.

As a general cooling lotion, and to ease the erythe after ultra-violet radiation (when erythema ou to be produced), a calamine and zinc oxide lotio invaluable, and may be dabbed on the affected a two or three times daily. The need must be impres upon every patient of thorough washing after e defæcation with some soap such as the germici soap of Parke, Davis, or Crooke's Collosol argent soap. After this the parts should be gently dr with salicylic acid wool and calamine lotion appli

Should any cracks or excoriations persist—a they often will, so that patience and perseverance requisite—then the use of an ointment such as following is recommended:—

℞	Hyd. subchloridi	2 drachms
	Bismuth subnitratis	1½ drachms
	Tr. aconiti	8 minims
	Glycerini	2 drachms
	Unguenti sambuci	up to 1 oz.

to be used night and morning.

When a paroxysm of irritation is threatened 2 per cent. carbolic lotion with spirit and rosewa will often abort an attack. The lotion should be k at the bedside. Pinching the irritable parts does mu less harm than scratching, and affords equal reli patients will soon learn the importance of t suggestion. Should the parts get sodden with characteristic unpleasant smell, dry calomel pow will prove serviceable.

Coming alike under general dietetic and spec treatment the value must be remembered of recou to spas like Harrogate, Luchon, Aix-les-Bai Schinznach, and many others. Here special appara directs a fine rose spray of warm sulphur wat once daily, for five or ten minutes locally agai the irritable and often excoriated anal region, affordi very great relief. The ordinary routine spa treatm will certainly also be of benefit. In cases of pruri where the cause is believed to be bacterial, vacc treatment must be borne in mind. An autogen vaccine may be prepared from a culture made fr scrapings taken from the affected anal area. For details and dosage of this one must be guided by bacteriologist.

Radiological Therapy.

The treatment of obstinate pruritus calls for w in which the dermatologist may find a useful coll orator in the physiotherapist. Radiology offers the dermatologist one of the most valuable adjuva in the treatment of pruritus ani et vulvæ. It is agent which eases the hyperæsthesia and allays irritation, and inasmuch as it possesses a stimul and bactericidal action it has a definite curat influence; used with intelligence, it is incapable producing any harmful effects. In pruritus, as many skin diseases, nearly a 50 per cent. benefit obtained if general irradiation by ultra-violet li of the whole body be added to local treatment, wh there is not only the bactericidal and other lo action, but there is, added to it, the general buildi up of the resistance of the patient which has be lowered by the continuous irritation and often resultant insomnia. The probability of success increased by half as much again through giving general body bath, twice or three times weekly. these baths the calcium content of the body is rais Dr. Agnes Savill [1] says: "Calcium lactate is so of useful in these cases"—which may be the rea for the good effect of the general body bath of ult violet light radiation. Ultra-violet radiation exe a biological action in the neighbourhood of int

[1] THE LANCET, 1929, i., 731.

ithelial nerve-fibrils, and if the pruritus be caused the *Staphylococcus albus*, *Streptococcus fæcalis*, *cillus coli communis*, or such mycetes as the idermophyton or trichophyton, then the lethal ect of radiation will readily account for them.

The affected area should be viewed with a magnifyg lens in a good light, and possibly tested with a all ultra-violet light, through a Wood's filter, in der to show any slight cracks or minute fissures to demonstrate the presence or absence of fungoid sease. Scrapings should be taken, and other ans for pathological examinations conducted, so to furnish the bacteriologist with all the material quired, and if, as will often happen, a negative port be obtained, examinations should be repeated veral times.

The patient should be prepared for local treatment. France, especially since treatment with the various ms of rays has come into use, shaving is usual ere the conditions have invaded the hairy skin. The rts having been shaved, they should be thoroughly ansed with soap and water and carefully dried. y crusts should be removed with the hands, in bber gloves if preferred, the parts should be smoothed t, and held apart so that the folds or deeper parts the recesses may become exposed to the treatment.

The treatment must of necessity vary with each lividual, and with the length of time which the ease has lasted. It should begin with an exposure ultra-violet radiation. The most convenient method application to these regions is by means of the omayer water-cooled lamp. It is impossible to down the precise dose, as there are so many tors which vary it. The lamp may be used at a tance of two or three inches, with a four-minutes posure, or it may be placed in contact with the n, the duration of the exposure varying inversely th the square of the distance. After a period rying from four to six hours a reaction and an rthema should appear. In pruritus vulvæ the tient should be warned that this reaction may be fficiently severe to render it advisable that she ould stay in bed for a day—possibly two days, t her previous sufferings will usually cause her erfully to assent to a temporary suspension of her lking activities. The counsel of perfection is that second application of ultra-violet rays should e place as soon as the erythema has subsided, l the distance remaining the same the time should increased by one or two minutes, according to the asure of erythema produced. Where, owing to patient living far away from the practitioner, from any other cause, the successive treatments not be regulated by the disappearance of the thema, then it has been found a useful rule give one ultra-violet ray treatment in the first ek and two treatments in the second, and one atment every week thereafter. Six or twelve atments are usually needed. The first treatment ays irritation to some extent, not because all the teria or fungi are destroyed or other cause removed, t because the light acts as an analgesic to the nervelings. Ultra-violet rays will often heal the small cks and fissures so often revealed when the rays passed through a Wood's filter. Once recognised y are easily cured by the application of the ap in contact with the lesion, employing a quartz plicator. It must be repeated that the healing these cracks is essential to successful treatment. the time of treatment the patient should be told expect an erythema to appear, and the lotion y be given to allay the irritation. This irritation, should be explained, is a necessary and salutary concomitant of the treatment; if this warning be not given, the patient may complain of a "burn."

The toilet of the pruritic area is of the first importance. The area must be kept scrupulously clean—there is much to be said for the universal use of the *bidet*, rarely seen in our country. The lower bowel must be kept empty by any mild aperient to which the patient may be accustomed or by an enema or glycerin suppository. In some cases a course of Plombière douches twice or three times weekly is of great advantage.

X ray treatment of pruritus continues to be a success; its disparagement has sometimes come from those without adequate experience, based upon some improper employment. In THE LANCET nearly six years ago, in one of the special articles on Modern Technique in Treatment, a paper by Dr. Louis Savatard contains the following passage:—

> "Radiation by means of the X rays I now use as the routine method of treatment for pruritus ani. Not only have the rays a marked antipruritic action, but they also reduce induration of the skin. X rays seem to have entirely suspended surgical division of the nerves, and not a few cases which have recurred after operation have remained permanently well after but a few exposures to the X rays." [2]

Our own experience is that X rays are of the utmost value in pruritus, especially in cases of long standing. The rays are directed into the anal area, perineum, and, in woman, to the vulvæ. The treatment may be given with the patient lying on the side on a couch, but I (F. H. H.) have found it more convenient to use a special stool invented by Curtis Webb, which can be placed over the X ray tube. In the seat is a circular aperture, $4\frac{1}{2}$ inches in diameter, through which the rays are directed. When the patient is seated on the stool the affected area can be accurately centred and the cheeks of the buttocks easily separated and maintained in position. In males the testicles are protected by a sheet of lead on the seat. The best results have been obtained with fairly soft rays given in divided doses. I use an equivalent spark gap of 5–6 inches, unfiltered, for the first three treatments, and for the last three a filter of 1 mm. of aluminium. Six doses of 1/6 β are given, either daily or spread over a fortnight, as the severity of the case demands. For various reasons there is a danger of sterilising patients, but that this cannot be easily guarded against in women seems to me without foundation.

Other electrotherapeutic measures have been used in the treatment of pruritus. Dr. J. M. H. MacLeod speaks well of zinc ionisation, and both here and in the United States of America it is our personal experience that static electricity has been used with considerable advantage. It is applied by means of vaginal or rectal glass vacuum tubes which are energised from the static machine. Its application is sometimes immediately effectual, often giving an instantaneous relief from the itching. The smallest size tube should be used at first, and the larger ones gradually substituted in succeeding treatments. It may be that the mechanical stretching of the anal area is of service. Dr. Agnes Savill devised a specially shaped tube, large enough to fit over the entire vulvæ. It is specially indicated when there is much swelling. It is pressed upon the swollen part and held in close contact. The treatment should be repeated daily. Both the vacuum tube for external use and the vaginal or rectal tubes for internal application, already mentioned, can be energised by the more familiar high-frequency machine and the results obtained may be equally good; but a careful

[2] THE LANCET, 1924, ii., 923.

comparison will show that the current is infinitely more agreeable to the patient when derived from the static machine.

The list of remedies to be used with advantage in the treatment of pruritus is by no means exhausted, as can be believed when its manifold causation is recalled. There are many therapeutic measures of which we have no personal knowledge, such as the destruction of the nerves at the point of their entry into the skin, and the injections of alcohol as described by Dr. Harvey B. Stone. The thickened peri-anal skin has been thinned by various applications, such as pure carbolic acid, solid CO_2, and even, under general anæsthesia, by the actual cautery.

Doubtless many remedies have been tried of which we have never heard, but the measures outlined, which we have actual experience of, if carefully applied and if painstaking choice is made between them, used separately or in combination will usually in the end achieve success.

ABDOMINAL TORSION OF OMENTUM.

By Michael J. Smyth, M.Ch. N.U.I., F.R.C.S. Eng.

ASSISTANT SURGEON TO HOSPITAL OF ST. JOHN AND ST. ELIZABETH; LATE FIRST SURGICAL ASSISTANT AND REGISTRAR, LONDON HOSPITAL.

The seven cases recorded below are examples of a rare variety of torsion of the great omentum—sometimes referred to as a true or pure intra-abdominal torsion. Five of the cases have been taken from the post-war records of the London Hospital. A sixth has been kindly supplied by Mr. C. J. MacAuley, of Dublin, who has already reported a case, while the seventh was operated upon by the writer at North Middlesex Hospital, Edmonton. Four of the cases answer to the common conception of torsion of omentum, inasmuch as the whole or a large portion of the structure was involved in each. In the other cases small or isolated portions only were affected, yet symptoms were severe enough to determine operative treatment. For this reason, apart from the rarity of the condition, it was thought advisable to include all the cases in this series.

As surgical text-books in the main do not distinguish between the different varieties of the condition, I shall consider briefly what classification has been arrived at, and what exactly is meant by pure intra-abdominal torsion.

Hernial Variety.—The great majority of cases of torsion of omentum occur in association with right-sided inguinal hernia. Other varieties of hernia, including ventral and umbilical herniæ which so often accommodate omentum, rarely figure as complicating factors. In the hernial variety torsion may affect the intrasaccular, the intra-abdominal, or both portions of the omentum. If a hernia be present and the twisted omentum shows no direct communication with the sac, the hernia is nevertheless suspect, and the case is ruled out of the category of pure intra-abdominal cases.

Abdominal Variety.—If torsion occurs and no hernia be present the condition is known as "true or pure intra-abdominal torsion." Such cases may, however, be complicated by intra-abdominal lesions such as appendicitis, pyosalpinx, and ovarian cysts, or they may arise without any apparent complication. The term "pure intra-abdominal torsion" would be better reserved for those which show no intra-abdominal complications whatever. With this slight modification, Cowell's classification would read: 1. Hernial—(*a*) intrasaccular, (*b*) intra-abdominal, (*c*) combine 2. Abdominal—(*a*) pure intra-abdominal, (*b*) associat with disease of abdominal or pelvic organs.

Abdominal torsion of omentum is undoubtedly rare lesion, but not so rare as was formerly suppos Before Cowell's review of the subject—a revi covering the period 1882–1924—not more than 1 cases had been recorded, and of these only three we contributed by British surgeons. His excellent pap has evidently borne fruit, for in the five years sin it appeared almost as many cases again have be added to the literature, a majority now coming fr British surgeons. MacAuley has had the uniq experience of dealing with three cases, in one of whic however, a hernia was present, while Wakeley recor two typical cases which came under his care.

There is hardly a case on record where diagno has been successfully made, yet the majority of ca have been recorded by surgeons of great experien The condition is most apt to be mistaken for acu appendicitis, acute cholecystitis, and sometimes ev for acute perforation of a peptic ulcer. Absolu accuracy in diagnosis is not of paramount importan provided, of course, that operative and not conserv tive treatment is adopted.

Pathology.

The strangulated mass varies in size. The wh of the omentum may undergo torsion, but the pa most frequently affected is the right side. Sometim an isolated tag or a so-called accessory omentum all that is found to account for symptoms. T condition in which the mass is found depends on t time at which operative treatment is undertaken. the earlier stages it is more or less compact, a varies in colour from dark red to purple or bla Later on it may show signs of disintegration, wi perhaps the addition of local or diffuse peritoni probably as a result of infection from the bow The mass adheres to the neighbouring viscera a the parietal peritoneum, but so lightly that gen insinuation of the finger suffices for separation. Su delicate adhesions are to be distinguished from t permanent organised ones of past inflammato trouble or perhaps a previous laparotomy. The m is attached at its central or colic end by a pedi which has undergone rotation a number of tim varying from one to ten. The pedicle also varies size; usually it is about the thickness of a fing but if the twists can be undone it thins out consid ably, and transfixion is thereby facilitated. Th may, of course, be two pedicles, an adhesion formi the basis of the second. Blood-stained exudate the peritoneal cavity, the natural sequel to strangu tion of any abdominal organ, is present in all cas

MOVEMENTS OF THE OMENTUM.

The great omentum has long been known as t "abdominal policeman." This is a nice metaph but the probabilities are that the policeman is less policeman *in esse* than *in posse*. The omentum itself should be incapable of movement. Microscop ally there is no muscular tissue in its constituti except that in its blood-vessels. These are neith large nor numerous, and to expect them, as has be suggested, to exert a material influence on the positi of the omentum is to make too great a demand up a very small amount of muscular and elastic tiss Rather does it seem that its position at any time determined by forces outside itself, such as moveme

* Vick's interesting case (Brit. Med. Jour., 1911, i., 622) not included in this list.

the body in general, and in particular the action the muscles of the abdominal wall and of the aphragm, and the movements of the muscular scera and intestines to which it is attached or th which it comes into contact. A healthy omentum ould move on other healthy serous surfaces as ell-oiled wheels on one other, but if, by virtue of s dimensions and the forces which control its sition, it is brought in contact with the blemished rface of an inflamed organ it will offer the latter a otective attachment. Such attachment may velop into organised adhesion which, if slender or alk-like, will not interfere with the play of movement cessary for torsion, but may act the part of a second dicle. On the other hand, adhesions that are oad and firm or numerous will so seriously embarrass e omentum that rotation will probably be out of e question.

THEORIES OF TORSION.

Many theories have been advanced to explain dominal torsion of omentum. Payr's views are sed upon venous congestion and spiral twisting the veins around the arteries, the elastic tissue in e coats of the latter being then relied upon to aid bringing about the necessary rotation. Fagge, his Bradshaw lecture on axial rotation, points out at such a theory presupposes the presence of venous ngestion, a condition which is really the result d not the cause of torsion; and that in the case an organ which has undergone torsion both arteries d veins are alike twisted in the pedicle. Fagge's searches further show that arterial circulation tends, anything, to have a limiting and not an encouraging luence on the rotation of pedicles. It might be ded that if the theory of venous congestion did tain, then one would expect torsion of the testis cases of varicocele to be a commonplace of surgery. Other theories lay stress upon congenital malfor- ation of the omentum, inflammatory changes in its ucture, and increased intestinal peristalsis. It ay be that there is a congenital tendency to pedicle rmation. Prof. William Wright inclines to the view at the omentum is of the nature of an overgrown pendix epiploica, and states that if appendices piploicæ are carefully examined and stretched out the full extent of their structure it will be found at their free border is much longer than their rder of attachment. Looked upon in the light of overgrown appendix epiploica, or perhaps even aggregation of these structures, it is conceivable at the omentum might occasionally display a ngenital tendency to pedicle formation, but this at st is mere conjecture. Incidentally, appendices piploicæ themselves sometimes undergo torsion.

The view here taken is that before intestinal ristalsis or body movement can bring about torsion the omentum, some deviation from the normal ucture is necessary—a deviation tending to bring into line with other abdominal organs and tumours hich are liable to rotation. A normal healthy entum, spread apron-like across the viscera, should t readily lend itsef to torsion, but unevenness of ucture, a localised concentration of tissue to vide, as it were, the bulk whereon the forces that ng about torsion can have purchase, and pedicle rmation, are factors which will give the omentum whole or in part the semblance of a tumour hanging ely in the abdomen.

'That such a tumour should by mere alteration of the sition of the body, or by mobility imparted to it by a tault of the bowels, spin round and twist its pedicle, is as nprehensible as the fact that a good weathercock moves varying directions under the influence of the wind" (and-Sutton).

In this alteration in structure, inflammation with its consequent fibrosis and matting of tissue will no doubt play its part; and to this may be added the factor of adiposity, for the condition occurs most frequently in stout people. Pedicle formation may trace its origin to congenital tendencies, but the probabilities are that this is also a pathological change, the altered omentum dragging upon its attachment and fashioning a pedicle of its own. The writer has had the opportunity of examining only two specimens of torsion of the omentum; both were fat-laden and showed definite signs of chronic fibrous change and matting of structure. Evidence in favour of this theory was given recently by a patient with acute left-sided pain, who was found at operation to have torsion of the left border of the omentum; in the twisted mass were found two tumours which proved to be accessory spleens.

The same forces which bring about torsion in the case of a single pedicle produce torsion in double pedicles. Here the intervening mass of omentum is anchored to two comparatively fixed points, and is rotated on its longitudinal axis in much the same way as a handkerchief is swung around between the hands when held at opposite corners.

It does not necessarily mean that, torsion having once begun, the affected portion continues steadily in its rotation until all slack is taken up and there is a sudden and absolute obstruction to the blood-supply. There is reason to suppose from a study of the histories of recorded cases that the lesion is primarily recurrent or chronic, and that the acute manifestation of torsion is but the final stage in a condition which has been maturing for some time. That is, torsion is of gradual evolution; a twist now and a twist again, some pain no doubt being caused by partial obstruction to the blood-supply, but the severe pain of strangulation being deferred until thrombosis of the supplying vessels is absolute. Such, according to Moynihan, is what happens in the analogous conditions of torsion of the spleen and ovarian cysts.

"In neither does rotation of the pedicle take place suddenly. In cases of ovarian cyst the movements of the whole of a large and often adherent cyst is impossible. The acute change is not in the twisting of a pedicle, but in the thrombosis of vessels which have long been twisted."

Clinical Features.

The patient, male or female, usually stout and of about middle age, is seized with an attack of acute abdominal pain. There may be a history of previous attacks. The pain is moderately severe, though not generally so severe as that of acute appendicitis. It tends to increase in severity, is not relieved by homely remedies, and is made worse by purgatives, even though the bowels be well opened. As the right border of the omentum is the part most frequently involved, the pain is referred to the right iliac or right para-umbilical region, but it may be referred to the right hypochondrium, the epigastrium, or the left side of the abdomen, varying with the situation of the twisted part.

The patient does not look ill; in fact the general condition is not in keeping with the abdominal upset. There is slight fever, 99°–100° F.; the pulse-rate rarely exceeds 120, while it is usually below 100 and may be as low as 80. Tenderness and rigidity are manifest over the site of the twisted mass. Some patients exhibit a degree of tenderness altogether out of proportion to the underlying lesion. This is in all probability due to involvement of the anterior parietal peritoneum, which shows inflammatory reaction at the site of adhesion. In torsion of the whole or a large portion of the omentum, rigidity

may be widespread, but this is unusual. The mass may be palpable if of sufficient proportions and if rigidity be not too marked. It is not firm to palpation, nor are its limits well defined. Some writers assert that a lateral mobility of the tumour can be demonstrated, but this statement must be received with reserve, for a mass of twisted omentum that is palpable will be at any rate adherent to the anterior abdominal wall.

Differential Diagnosis.

Acute Appendicitis. — The condition is most frequently mistaken for acute appendicitis. In typical cases of both there are, however, some features which may help to distinguish between them.

(1) While either lesion may occur at any age, acute appendicitis is more a disease of youth; torsion of omentum more a disease of middle age.

(2) Nausea and vomiting, if present, are said to precede the pain in omental torsion, whereas the reverse obtains in acute appendicitis.

(3) In acute appendicitis the pain is first referred to the umbilical region and later settles in the right iliac fossa, with a maximum degree of tenderness over McBurney's point; in torsion of omentum the pain is at all times referred to and maximum tenderness is present over the site of the twisted mass.

(4) In torsion the palpable tumour is present early, whereas in acute appendicitis time is required—two or three days—for its formation. The tumour in acute appendicitis is firm and circumscribed and is not mobile.

(5) Acute appendicitis, with or without abscess formation, is accompanied by constitutional disturbance in keeping with a toxic condition. The patient looks and feels ill, and the temperature and pulse are higher than in omental torsion.

A definite leucocytosis must not necessarily be taken as indicative of acute appendicitis. The great omentum is rich in white cells, and this content is markedly increased in acute inflammatory and traumatic conditions of the abdomen. This may or may not have a bearing upon the question, but the fact is that cases of omental torsion in which a blood-cell count has been done show a leucocytosis ranging from 12,000 to 18,000.

Acute Cholecystitis.—Pain and tenderness are definitely referred to the right hypochondriac region with catching of the breath. The pain in omental torsion does not radiate to the back or right shoulder. The temperature in acute cholecystitis rises to 101° F. or higher. As local rigidity disappears it may be possible to map out the enlarged and tender gall-bladder. Later there may be evidence of jaundice. A history of dyspepsia will also help.

Acute Perforation of a Peptic Ulcer.—The widespread rigidity exhibited by some cases of omental torsion, combined with the small degree of change in temperature and pulse-rate, may, if the case is seen soon after the onset of illness, lead to confusion with perforation of a peptic ulcer. Immediately after perforation the temperature drops to subnormal, and the pulse-rate may even be slower than normal for the individual, but when this initial stage has passed the temperature and pulse-rate rise steadily, the pulse becoming thready as time goes on. The onset of the illness in perforation is marked by agonising pain, the patient looks very ill, and with each succeeding hour his condition becomes more desperate. Under anæsthesia the mass in omental torsion will no doubt become palpable, for these are the cases in which the whole or a large portion of the omentum is involved. This was a point which enabled Wakeley to alter th diagnosis in his second case.

These are some of the points of guidance in typic cases, but abdominal cases, whatever their natur have a habit of not being typical, and the mai point at issue is whether operation is to be undertake or not. Needless exploration is, of course, to l deprecated, but conservative treatment demands least the exclusion of any serious abdominal lesio requiring operation. With urgent symptoms an symptoms which give rise to doubt, one is not infr quently driven to exploration. There is one dang in omental torsion, and that is, that while mistakin the case for one of acute appendicitis, conservati instead of operative treatment may be adopte There are some surgeons who defer operation in case of acute appendicitis once a certain time limit ha elapsed from the initiation of the attack, sometime too, in the event of finding what is adjudged to be a appendix abscess. In the hands of its distinguishe advocates this line of treatment has given cause f satisfaction, but it demands certainty in diagnosi and the benefits of hospital are not available to a A delay of a few days may not make a vital differen to an uncomplicated case of omental torsion, thoug the sooner operation is undertaken the better. W can, however, imagine the danger of delay in such case as No. 7. The strangulated omentum woul no doubt, have provided an excellent culture mediu for the organisms from the acutely inflamed appendi of which it was a complication.

Cases.

1. *Mr. W. S. Perrin's case*, a married female, aged was admitted to the London Hospital on Oct. 25th, 192 Three days before admission she had complained of sudd acute pain in the abdomen, chiefly in the umbilical a right lumbar regions; the pain had been intermittent a at first severe, but had eased off later. It was still prese on admission to hospital. There was nausea but no vom ing, and the bowels were very loose (four to five motio daily). She gave a history of many similar attacks duri the three previous years, but none were so bad as the prese one. In the attacks the patient could feel a lump to t right of her umbilicus, and she lay in bed for a week un the pain and lump subsided. The lump never complet disappeared, but between the attacks she felt quite w The pain had no relation to food nor was there ever any si of jaundice, and there was no trouble with micturitio There were no previous illnesses of any importance.

The temperature was 100·4° F., and the pulse-rate 1 The patient was a large obese woman. The tongue w slightly furred. The abdomen was greatly distended, a there was marked tenderness and rigidity to the right the umbilicus and in the right lumbar region. There was hyperæsthesia.

Operation.—The abdomen was opened by a right upp paramedian incision with retraction of the rectus outwa A large piece of twisted and strangulated omentum w found adherent to the transverse colon. The pedicle w ligatured and the mass removed. The peritoneum of t anterior abdominal wall was very much inflamed oppos the site of the strangulated omentum. The gall-bladd duodenum, and stomach appeared normal. Enlarged glan were felt in the portal fissure. The incision was prolong downwards and the appendix found after some difficul Appendicectomy was performed.

The after-progress of the case was satisfactory, and t patient was discharged from hospital on Nov. 10th, 192 I have seen this patient in the follow-through departme of the hospital. She has been very well since her dischar and says that the lump never completely disappeared un she had her operation.

Microscopic findings.—(1) Hæmorrhagic infarction omentum. (2) No active inflammation in slightly fibro hypertrophied appendix.

2. *Mr. James Sherren's case*, a married female, aged engaged in housework, was admitted to the London Hospi on Sept. 24th, 1923. Four weeks before she had had slight attack of pain in the upper abdomen, follow exertion. Three days before there had been recurre of a similar pain, which was, however, more severe, a doubled her up. The pain was situated just above

nbilicus and, though it eased off somewhat, it continued ıtil the time of her operation; it had no relation to food, ıd was relieved by resting in bed. There was no nausea ır vomiting. The bowels had been opened since the ginning of the attack, and there was no trouble with icturition. For 16 years the patient had suffered from tacks of pain coming on a few minutes after meals and sting for a few hours. This pain was quite distinct from e acute pain for which she was admitted to hospital. was situated much higher in the epigastrium "just below e breast bone," came on after each meal, and remained th her for two or three weeks with two to three months' ee intervals. It was not associated with vomiting, and she d never been jaundiced.

Examination.—The temperature was 98·8° F., and the lse-rate 96. She was a spare woman. There was a thick r on the tongue and fœtid breath. Tenderness and rigidity re marked in the epigastrium. A small tense swelling ıs palpable a little to the right and above the umbilicus.

Operation.—A right upper paramedian incision was made d a poorly-developed rectus drawn outwards. A dark emorrhagic mass, a little larger than a walnut, was found herent to the falciform ligament and to the anterior ıll of the stomach. This proved to be a portion of the eat omentum which had undergone torsion and was aling off a perforating ulcer of the stomach. The gall-adder appeared healthy. The appendix was long, fibrosed, ıd tacked down by numerous adhesions; it was removed. ıe twisted mass was separated from the great omentum d partial gastrectomy was then performed, the ulcer-aring area of the stomach being removed, together with e adherent portion of the strangulated omentum.

The patient was discharged well on Oct. 15th. Seen in e follow-through department six months ago she said she d had excellent health since her operation.

Microscopic report.—(1) Chronic progressive peptic ulcer stomach. (2) Fibrosis and muscular hypertrophy of pendix. (3) Hæmorrhagic necrosis of a portion of the ıentum adherent to a chronically inflamed falciform ament.

3. *Mr. Hugh Cairns's case*, a Hebrew male, aged 57, was mitted to the London Hospital on June 20th, 1925. On e day before admission he had a gradual onset of pain the right side of the abdomen. There had been no usea or vomiting. At 5 P.M. he had taken castor oil, d during the night supplemented this with Glauber's lts. The bowels were opened, but pain got worse. His mperature was 98° F., and his pulse-rate 94. He was nder and somewhat rigid in the right iliac fossa.

Operation.—The abdomen was opened by a muscle-litting incision in the right iliac fossa. The appendix ıs injected, distended, and somewhat œdematous-looking, th fibrinous flecks on the serosa. Appendicectomy was rformed. A tag of great omentum, the shape of its pedicle, ıs discovered hanging freely movable within the abdominal vity. The strangulated tag was ligated and removed. ıe patient did well and was discharged on July 2nd. e reported to the out-patient department on March 17th, 27, and was very well.

Microscopic findings.—(1) Subacute inflammation of pendix. (2) Congestion and hæmorrhage in omentum.

4. *Mr. Alan Perry's case*, a married female, aged 27, egnant three months, was admitted to the London spital on Sept. 12th, 1925. Three days before the tient had been seized with sudden acute pain in the right ıc fossa. Vomiting and diarrhœa had accompanied the set of pain. The vomiting ceased on the first day, and e diarrhœa on the second. There had been no appetite two days. There was no pain on micturition and no tory of previous attacks of pain. The patient did not k ill. Her temperature was 99·4° F., and her pulse-rate 3. Her tongue was furred. Tenderness, rigidity, and a np were present in the right iliac fossa, and very slight derness in the left iliac fossa.

Operation.—A right paramedian incision was made, and nplete torsion of omentum discovered (three turns). e pedicle was ligatured and the twisted omentum excised. Recovery was uneventful, and the patient was discharged convalescence Sept. 24th, 1925.

5. *Mr. Russell Howard's case*, a married female, aged 33, rsing a baby 5 months old, was admitted to the London spital on Feb. 1st, 1927. Three days before admission patient had complained of sudden pain to the right of e umbilicus, not very severe but constant. There had en no vomiting, and the bowels had been open each day ce the onset of illness. Micturition was normal, and she d never had a previous attack. She was a healthy-looking man. Her temperature was 99° F., and her pulse-rate 84. r tongue was furred, and her heart and lungs clear. tender palpable lump was present in the right hypo-ondrium. Graham's dye test showed no evidence of olecystitis.

Operation.—On Feb. 10th an upper right rectus incision was made. A hard brown lump, 1 by 1 by 1 in., was discovered adherent to the anterior abdominal wall and to the stomach. On withdrawing it from the abdomen it was found to be a portion of the omentum which had undergone torsion. A small clamp was put on the stomach end of the mass, its pedicle transfixed, and the mass removed. The raw surface on the stomach wall was peritonealised by fine catgut and the abdomen closed. The patient made a good recovery, and was discharged well on Feb. 26th. In reply to a request to come to the follow-through department of the hospital she wrote to say that she was very well and had had no further trouble since operation.

Microscopic diagnosis.—Chronic inflammation and areas of necrosis of adipose tissue in portion of omentum.

6. *Mr. C. J. MacAuley's case*, a youth, aged 18, was admitted to the Mater Misericordiæ Hospital as an urgent abdominal case on Feb. 17th, 1928. He stated that on the previous day he had been seized with a severe pain in the right iliac fossa. He had vomited once, and his bowels had not been opened since the onset of the pain.

He was a healthy-looking youth. His temperature was 99° F., and his pulse-rate 94. The abdomen was undistended. He referred the pain to the right iliac fossa, which area was extremely tender and rigid. It was noted that the right testis had failed to descend and that the right side of the scrotum was under-developed, but to this fact no particular significance was attached.

Operation.—A diagnosis of acute appendicitis was made and immediate operation carried out, the abdomen being opened by a right Battle's incision. When the peritoneum was opened some free fluid—slightly blood-stained—escaped. The parietal œdema which I had noted in previous cases was not here observed. On seeking for the appendix a large mass was felt and easily delivered into the wound. This proved to be a mass of twisted omentum, purplish in colour, with an abdominal testis attached to its lower end. The whole mass was removed without much difficulty, but in the course of manipulation the adhesion of the omentum to the testis, which I was most anxious to preserve, unfortunately gave way, spoiling what would otherwise have been an unique pathological specimen. The abdomen was closed in the usual manner. The patient made an uneventful recovery and was discharged from hospital on March 3rd, 1928. There was no hernia in this case.

7. *Author's case*, a male, aged 44, was admitted to the North Middlesex Hospital at 4 P.M. on August 25th, 1925. He had been awakened from his sleep in the early hours of that morning by acute abdominal pain. He had vomited, and taken some brandy. This had failed to give relief and had made him vomit again. The pain had been very severe, and felt mainly across the lower abdomen; later it had seemed to settle in his right side. He stated that he had suffered from abdominal pains from time to time, but never anything so severe as this—never severe enough to make him lie in bed. His bowels were regular and had been opened on the previous day.

He was a tall spare man, who looked ill. His temperature was 102·8° F., and his pulse-rate 128. The abdomen was slightly distended, and did not move well on respiration. Definite tenderness and rigidity were present in the right iliac fossa and right para-umbilical region. The hernial orifices were clear, and there was no history of rupture. On rectal examination there was slight tenderness on the right side of the pelvis. The lungs were clear and the heart sounds weak. A diagnosis of acute appendicitis was made.

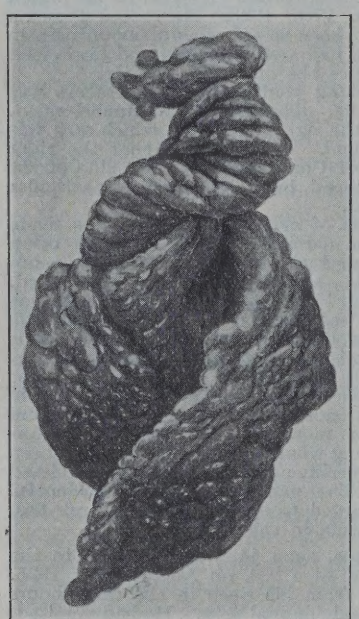
Under anæsthesia it was thought that a lump could be felt in the right iliac fossa, but this was so doubtful that I did not further consider it. The abdomen was opened by a muscle-splitting incision. The peritoneum looked dark and œdematous, and blood-stained fluid escaped on incising it. Immediately underneath lay the omentum, darkish-red in colour, adherent to the parietal peritoneum, the cæcum and the appendix. It separated easily from the parietes, and its adhesion to the cæcum and appendix was so light that when all three were delivered from the abdomen it had become almost completely detached from the other two. The appendix was swollen and acutely inflamed. For the moment it was covered with an abdominal pad and laid aside. On further withdrawing the omentum from the abdomen it was seen to have twisted upon itself several times. The twists were undone; as many as ten were counted, and even then the pedicle did not seem to be completely unrolled. The pedicle was ligatured and the twisted omentum removed. Appendicectomy was performed. Swabs on holders were passed down to the pouch of Douglas, and some odourless blood-stained fluid mopped out. The abdomen was closed without drainage. The appendix contained muco-pus and a large concretion; its mucous membrane was hæmorrhagic (see Figure).

The patient made an uneventful recovery, but remained in hospital six weeks for treatment of his cardiac condition.

A year later he met with a fatal accident, and Dr. A. W. Gregorson, assistant superintendent, North Middlesex Hospital, who performed the post-mortem examination, was kind enough to supply me with some details. "There was little trace of the great omentum except some vestiges near the splenic flexure. The cæcum was mobile and the peritoneum smooth at the site of operation. The liver was enlarged from the back pressure of a heart diseased in its valves and in its myocardium. Death was due to multiple fractures and a fracture of the base of the skull."

Treatment.

The treatment is removal of the twisted omentum at the earliest opportunity. No special difficulty attaches to the operation, and there is no recorded mortality in cases that have been operated upon early. It is on record that the twists have been undone and the omentum replaced, but such treatment is not to be advocated. If the strangulated part be viable the danger of recurrence is too great to be risked, as evidenced by the marked tendency of the omentum, even after removal, to resume its original twisted position. (See accompanying Figure.)



Author's case. Drawing of specimen made by Mr. W. T Shiels. Actual specimen measured 14 × 9·4 × 3·5 cm.

The main features of the case may not, in spite of careful consideration, lead to correct diagnosis, but they should at any rate determine that an exploratory operation be undertaken. A paramedian incision, with displacement of the rectus muscle outwards, is on the whole the best, for it allows of easy extension upwards or downwards, gives access to the majority of abdominal viscera, and rarely gives rise to subsequent weakness of the abdominal wall. It is an incision to be more strongly recommended than the pararectal, with displacement of the muscle inwards, for while the latter as a rule gives good access to the appendix it is not without its disadvantages. In the event of its extensive enlargement upwards or downwards, nerves get in the way and, even if recognised, may be damaged, with consequent weakness of the rectus or, in some cases, ventral hernia (Sherren).

There is strong evidence in favour of a recurrent or chronic condition of torsion of the omentum. If exploratory laparotomy be done to clear up recurrent attacks of vague abdominal pain, suspicion may not unnaturally be directed to the appendix, particularly if operation be carried out during a quiescent interval. The omentum should not be forgotten in the routine examination of the viscera, and any suspicious abnormality affecting it should be dealt with. Timely intervention will anticipate the possibility of acute torsion, and help much more towards the relief of pain in such cases than simple removal of a doubtful appendix.

I am indebted to the surgeons of the London Hospital; to Mr. C. J. MacAuley, surgeon, Mater Misericordiæ Hospital, Dublin; and to Mr. Spencer Mort, medical superintendent North Middlesex Hospital, for permission to publish the cases.

BENZYL-CINNAMATE TREATMENT O PULMONARY TUBERCULOSIS.

BY T. W. WADSWORTH, M.D.LIVERP., M.R.C.P.LON
HON. PHYSICIAN, CHEST HOSPITAL, LIVERPOOL;
AND
J. T. FLANAGAN, M.D. LIVERP., D.P.H.,
STIPENDIARY MEDICAL OFFICER TO THE HOSPITAL.

THE remarkable radiological improvement th has been noticed is the main reason for the followi account of the treatment of cases of pulmona tuberculosis with benzyl-cinnamate injections.

Method of Treatment.

Benzyl cinnamate ($C_9H_7O_2C_7H_7$ ($C_6H_5CH.C$ $COOCH_2C_6H_5$)), a natural constitutent of balsa peruvianum, is given by us as a 1 per cent. soluti in olive oil. We inject 5 c.cm. intramuscularly the usual site—namely, about 2 inches to 3 inch below the iliac crest—commencing laterally a giving successive injections slightly nearer the midd line. Injections are given daily for 12 days, follow by a fortnight's intermission, then 12 more dai injections, another fortnight's rest, and 12 mo injections. Then after an intermission of about s weeks the three series of 12 injections are repeate A rest from treatment of about three months followed by a further six series or courses injections exactly as the first six. The following the method of preparing the solution carried out b Mr. Rea, dispenser at the Chest Hospital.

Owing to the volatile nature of benzyl cinnamate it necessary to sterilise the olive oil before the medicament dissolved in it. This is done by heating 50 c.cm. of the in 100 c.cm. flasks at a temperature of from 120° C. 130° C. in a dry air steriliser for two hours. The necks the flasks should be plugged with a wad of sterile w wrapped in gauze. It is taken for granted that the ben cinnamate itself is sterile. It is solid at normal temperatur but may be readily liquefied by immersing the container a water-bath. The requisite amount is then weighed in

sterile measuring flask, and a sufficient quantity of the ɔoled olive oil added to make a 1 per cent. solution. Finally ıe solution is filled into 5 c.cm. sterile ampoules by means f a 20 c.cm. serum syringe.

The Table shows the result of the treatment in 3 cases. We have since added further subjects to

ase.	Courses of injections.*	Duration of phthisis in years before treatment commenced.	Result of treatment.		
			General condition.	Weight in lb.	X ray report.
1	7	7	Imp. ++	Same.	Very marked imp.
2	5	10/12	Imp. ++	+ 14	Marked imp.
3	3	6/12	Imp. ±	+ 4	Imp. l. lung; r. lung unch.
4	1	4/12	Died.	—	—
5	6	1	Imp.	Same.	Much imp.
6	6	5	Imp.	− 4	Definite imp. but suspicion of new cavity.
7	3	3	Imp. ±	Same.	Slight imp.
8	1	1	Died.	—	—
9	1	2	Died.	—	—
0	1	2/12	Died.	—	—
1	3	2¼	Imp. ++	+ 5	Very much imp.
2	1	1	Imp. ++	+ 8	One radiogram only.
3	6	3/12	Imp. ++	+ 42	Very marked imp.
4	3	11/12	Imp. ±	+ 14	One radiogram only.
5	2	10	Died.	—	—
6	3	1	Imp. ++	+ 29	No change.

* One course = 12 injections.
The duration of phthisis is estimated from the history of the te of onset of typical symptoms. Imp. = improved or provement. Unch. = Unchanged.

ır list but have not yet had time to assess their ogress. The treatment has been carried out under e not ideal conditions of a hospital in the centre of large city. The method appears safe, practically ıinless, easy, and cheap. It is not advisable to give is treatment in renal cases; in one patient recently e renal condition became worse after the injections. ecause the treatment was stopped the case has not ɔen included in the results.

Results.

Almost all the in-patients at this hospital, with the ɔception of those sent in for diagnosis, have advanced ıthisis, and all the cases dealt with in this article, th one exception, were in this category. The ɔception, No. 12, was attending a clinic with a rly quiescent type of phthisis when she developed large pleural effusion. She was immediately pirated on admission, and improved rapidly, the provement continuing on the benzyl-cinnamate ɜatment.

Five patients died. Four of these, Nos. 4, 8, 9, and , were so ill on admission that their death was a ıtter of early expectation. None of them had more an one course of injections—i.e., 12—and in two ɜes they were so ill that they could not be moved the X ray room. The fifth case (No. 15) was of ı years' duration, was complicated by gall-stones, d was mentally unsatisfactory. He had only two ırses of injections. It may be assumed that with ne of the patients who died was it possible to give air trial to the benzyl-cinnamate treatment.

The remainder of the cases (and all cases were ɔsen completely at random) showed evidence of ɑsiderable benefit from the injections. Cases 2, 5, 11, and 13 showed marked radiological improve- ɔnt. Cases 3 and 6 showed definite X ray evidence some improvement. Case 7 showed slight improve- ɔnt. Case 16, in the 13 weeks she has been in spital, has not yet shown X ray evidence of change, t has put on 29 lb. in weight. Case 1, with a tory of four years' active phthisis, was extremely ill, and has shown remarkable clinical improvement. She has been able to leave the hospital, and is now continuing treatment as an out-patient. Cases 2, 13, and 16 have also shown remarkable clinical improvement. Cases 3, 5, 6, 11, 12, and 14 have also improved clinically, but to a lesser extent. In Case 7 clinical improvement is doubtful. Cases 2, 3, 12, 13, 14, and 16 have increased in weight, most noticeably 2, 13, and 16.

The amount of sputum generally showed an increase at the commencement of treatment, with a subsequent decrease. No consistent effect was noticed during the treatment of these cases on the presence of tubercle bacilli in the sputum or on the temperature or blood pressure. It will be seen: (1) That usually at least three courses of injections were given before any definite improvement resulted. (2) That increase of weight has occurred principally in those cases of no longer duration than 12 months. (3) That definite clinical and very remarkable radiological improvement can be accomplished, even in very toxic and extensive and long-standing phthisis, such as we have had to deal with.

Our thanks are due to Mr. J. H. Mather, the hon. radiologist, for the valuable help he has given us.

A STUDY OF YEASTS

BY THE COMPLEMENT-FIXATION TEST.

By Kenneth Stone, M.D. Oxf., M.R.C.P. Lond.,
SENIOR ROSE RESEARCH FELLOW, ST. BARTHOLOMEW'S HOSPITAL; ASSISTANT PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN.

Between 1928 and 1930 a combined investigation was carried out at St. Bartholomew's Hospital, under the Rose Research Fund, with a view to obtaining evidence bearing upon the ætiology of lymphadenoma. In the course of this study an attempt was made to ascertain whether a mycotic infection is present in this disease, and a special search was made for the presence of micro-organisms of the yeast and sporothrix groups, by making cultures on Sabouraud's medium of affected glands and other tissues. As is well known, yeasts and yeast-like organisms occur on various vegetables in nature, are met with in air, and grow very readily on Sabouraud's medium. Differentiation is at present achieved principally by study of the cultural, morphological, and biochemical characters, with a result far from convincing. An attempt has accordingly been made to apply serology for this purpose, employing the complement-fixation test.

Previous attempts have been made to investigate the serological behavour of different strains of yeasts, but no practical method of classification appears to have resulted. Schütze,[1] in 1903, was unable to distinguish by agglutination and precipitin reactions the yeasts he investigated—certain yeasts employed for fermentation, and yeasts from corn and potato. He succeeded[2] in 1911 in differentiating the same organisms by the complement-fixation reaction. Lichtenstein,[3] in 1914, found that he could distinguish various kinds of saccharomyces and differentiate the torula group from the saccharomyces group by means of agglutination. Balls,[4] in 1925, found the precipitin method well adapted for use in differentiating between closely related species of yeasts and in showing relationships which are not brought out in the ordinary botanical classification. For the precipitin reactions in these investigations a yeast autolysate was used as antigen.

Mueller and Tomcsik [5] showed that extracts of many species of bacteria, prepared in such a way as to be as free as possible from coagulable proteins, contain substances which specifically precipitate with homologous immune sera and which produce skin reactions of the tuberculin type in infected animals, but do not induce antibody formation on repeated administration to rabbits. In 1914 they found that a similar "residue antigen" can be prepared from yeasts. The active material is a complex carbohydrate —"the yeast gum." Tomcsik,[6] in 1930, investigated the specificity of reactions obtained with this yeast gum. He studied 13 yeasts, 3 isolated from throat secretions from cases thought to be diphtheria, and 10 of the saccharomyces group. By cross-precipitation test five saccharomyces strains were apparently identical, whereas the remaining five were distinct. The results of complement-fixation tests were practically identical with those of the precipitin tests. Further, it was found that the results of agglutination tests, using suspensions of the yeast cells, were identical with those obtained by precipitin and complement-fixation tests using the yeast gum.

TECHNIQUE OF PRESENT INVESTIGATION.

1. *Preparation of sera.*—The sera used were prepared by Dr. Mervyn Gordon as follows: a full growth of the yeast on one slope of Sabouraud maltose agar was suspended in 10 c.cm. of saline and heated at 65° C. for 30 minutes, and 0·5 per cent. of phenol was added. Rabbits were injected with rising amounts of this suspension at weekly intervals for five weeks. Samples of serum were taken before each injection and compared. It was usually found that the best serum was obtained after four or five doses. With some yeasts a low titre serum only is obtained by this method; in these cases injections of the living organism may be successful.

2. *Complement-fixation technique.*—A quantitative test was used throughout, for only in this way can group fixation be detected; this was realised by determining the highest serum dilution at which the reaction was obtained. The technical details described in the *British Journal of Experimental Pathology* (1923, iv., 318) have been followed with minor differences of detail. In the early stages of the work the antigen used was a simple saline suspension of the organism. Experiments, however, showed that a saline washing of the yeast gave as strong reactions as the saline suspension, and that much sharper end-points were obtained. The work to be recorded was therefore carried out with antigens prepared in this way: the growth on one slope of Sabouraud maltose agar (age variable) was suspended in 10 c.cm. of saline; the suspension was allowed to stand for about five minutes, then centrifuged at high speed. The resulting clear supernatant fluid was pipetted off and used.

3. *Absorption tests.*—A suitable saline dilution of the serum to be absorbed was treated with a strong suspension of the yeast and the mixture incubated in the 37° water-bath for two hours. After centrifugation at high speed for one hour the upper layers of the supernatant fluid were removed and tested by the usual technique. It was found that absorption tests presented considerable technical difficulties, and so far they have proved satisfactory with thrush serum only. They could not, therefore, be used as a routine.

RESULTS.

1. *Identity of different strains of thrush.*—Cultures of the thrush fungus (*Oidium albicans*) were isolated from the throats of ten successive cases of the disease, and tested with a serum prepared against one of these strains. All specimens gave identical results, reacting to titre with this serum. The type of yeast most frequently obtained from lymphadenoma material, Type I., gave considerable group fixation with anti-thrush serum. The reaction was constantly found to be to half the titre of the homologous reaction. It was, therefore, important to show whether or not these organisms are distinct serologically by absorption of complement-fixing antibodies. Table I. records the results of such an absorption test. It will be seen that the thrush organism almost completely removes the antibodies from the thrush serum; absorption with the Type I. yeast produces a slig diminution only in this reaction. This result has be obtained repeatedly with another thrush serum.

None of the yeasts from lymphadenoma materi (with the sole exception of an organism obtained l culture of a pharyngeal swab from one patien from control material, or from the air, and none the specimens from the National Collection of Ty Cultures reacted to titre with thrush serum.

TABLE I.

Antigen.	No serum.	*Thrush serum unabsorbed.*

		Thrush serum absorbed by yeast, Type				
Nil ..	—	—	—	—	—	—
Thrush ..	A.C.	++ 25	++ 50	++ 100	— 200	— 400

++ = Complete fixation. + = More than 50 per ce fixation. +— = Less than 50 per cent. fixation. — = fixation. A.C. = Antigen control.

Many yeasts gave little or no reaction with thru serum and, with the exception of Type I., none ga more than a moderate group reaction. A simp complement-fixation test is therefore sufficient differentiate thrush from all the yeasts we have studie with the exception of Type I. This is readi distinguishable by an absorption test.

2. *Seven serological types so far determined.*—The yeasts studied have been obtained from lymp adenoma material, control material, and from the ai in addition, the following known pathogenic yeas and yeast-like organisms have been studie (1) thrush; (2) eight specimens of pathogenic yeas from the National Collection of Type Cultures; (3) t sporothrices of Beurmann, Schenck, Gougerot, a Jeanseln. When submitted to the complemer fixation test the following organisms were found to serologically distinct: (I.) Darbyshire: yeast fro lymphadenoma gland; (II.) Thrush; (III.) Toru Stoddart: No. 5 from the National Collection Type Cultures; (IV.) Skipp, A.: a *black yeast* fro lymphadenoma gland; (V.) Barber: yeast fro lymphadenoma gland; (VI.) Rowe: yeast fro lymphadenoma gland; (VII.) Beurmann's sporothri

Table II. shows the results of cross tests with the seven organisms and the corresponding sera. Tl titre of the reaction with the homologous organism given and a definite group reaction is indicate 0 = little or no reaction.

With but three exceptions, which remain for tl present unclassified, all the yeasts studied (58, includi 10 strains of thrush) fall into one or other of the seven groups, reacting to titre with one or other of tl seven sera.

Twenty-one lymphadenoma yeasts fall into fi groups—namely, I., III., IV., V., and VI., 12 them belonging to Type I. Twenty-four of t yeasts studied belong to this type, which contai three yeasts from the National Collection, several fro cultures of control material, and two obtained from t air. In the group of *black yeasts* (Type IV.) are tv organisms isolated from lymphadenoma tissu Six black yeasts were tested and all were found to identical. They include a yeast obtained from

vocain bottle, and the sporothrices of Gougerot d Jeanseln. Type III. (Torula Stoddart) contains no asts obtained from control material. It is composed two lymphadenoma yeasts and five other specimens pathogenic yeasts from the National Collection of

TABLE II.

	Serum—						
	I.	II.	III.	IV.	V.	VI.	VII.
I.	Titre 400	Group.	0	Slight group.	0	0	0

7.	0	Group.	Group.	Titre 1600	0	0	0
7.	0	0	Slight group.	0	Titre 800	0	0
I.	0	Slight group.	,,	0	0	Titre 1600	0
I.	0	0	,,	0	0	0	Titre 200

Darbyshire; II., Thrush; III., Stoddart; IV., Skipp. A.; V., Barber; VI., Rowe; VII., Beurmann.

pe Cultures. Type V. is that of a yeast isolated from case of lymphadenoma, which has proved to have thogenic properties of considerable interest. Two ner lymphadenoma yeasts and two specimens from ntrol material belong to this group. Type VI. nsists of two specimens only, both obtained from nphadenoma cases.

3. *The sporothrices of Beurmann and Schenck.*— yeast was found to react with an antiserum to the sporothrix of Beurmann; this organism is therefore quite distinct from members of the yeast group so far studied. It is worthy of note that by the complement-fixation test the sporothrix of Schenck is indistinguishable from that of Beurmann.

CONCLUSIONS.

1. By using a saline washing of the yeast as antigen the complement-fixation test can be applied in the identification of various members of the yeast and sporothrix groups. (2) Specimens of thrush (*Oidium albicans*), obtained from ten successive cases, gave identical results. By the complement-fixation test all belong to one serological type. (3) Specimens of yeasts obtained from other sources have been studied, and are shown to fall into five types. (4) The sporothrices of Beurmann and Schenck appear to be identical, and quite distinct from yeasts so far studied. The sporothrices of Gougerot and Jeanseln appear to be identical with black yeasts obtained from other sources.

The work was carried out under the direction of Dr. Mervyn Gordon. My thanks are due to him for permission to publish the results, and to his laboratory assistant, Mr. J. Haegerty, for invaluable practical help.

CLINICAL AND LABORATORY NOTES

SEVERE DIPHTHERIA.

AN ACCESSORY METHOD OF TREATMENT.

BY B. A. PETERS, M.D. CAMB.,

MEDICAL SUPERINTENDENT, HAM GREEN SANATORIUM AND HOSPITAL, BRISTOL, AND LECTURER IN FEVERS, UNIVERSITY OF BRISTOL.

THE accessory method of treating diphtheria which here outlined has been tried on 730 cases during severe epidemic with encouraging results, the ath-rate being only 2·3 per cent., exactly half that the immediately preceding 600 cases. It is based the theory that diphtheria toxin (like other true ins) acts as a positively-charged colloid, causing culation or gelation of the blood and tissue teins, and that the pathology of the disease is, at st in part, explicable by the collection of these cules in the capillaries of important viscera. We nk we have confirmed this theory by the dark und examination of capillary serum in severe es. Antitoxin only neutralises toxin; it does not tore the floccules to their normal state of disper- n and electrical charge. The use of peptising nts (as suggested by McDonagh's work) would be easonable method of overcoming this.

n severe cases in addition to the administration of full es (30,000 to 40,000 units) of antitoxin, of which part is en intravenously, 5 to 7 ounces of 20 per cent. glucose ution is given intravenously on admission. This produces immediate improvement in the patient's condition. asionally a rigor may follow its use, but this never seems do harm. The patient is also given one or two doses of tramine (0·125 g.) intramuscularly on succeeding days. following mixture is given four-hourly by mouth until urine is alkaline to litmus: sod. bicarb., grs. 30; pot. arb., grs. 5; calcii carb., grs. 7½; aq. menth. pip. to one ounce. Four to eight grains of thyroid are given daily and 20 minims of tinctura lodi mitis by mouth in milk four-hourly. These two drugs are given until the urine is free of albumin; this sometimes takes three or four weeks, These drugs are extremely well borne, and no evidence of intoxication has shown itself, if the albuminuria is taken as a guide. If the patient is inclined to vomit in the second week the subcutaneous injection of a pint of 3·6 per cent. glucose will usually check it.

The treatment in our hands has undoubtedly saved a number of desperately ill patients, and appears to diminish the more deadly forms of paralysis. No fatal case of diaphragmatic paralysis has occurred in this series. The preceding 600 cases provided four such cases, although many of these received intravenous serum. The intravenous injections are sometimes difficult, and frequently need the exposure of a vein under 2 per cent. novocain. We are using two 20 c.cm. record syringes, which are filled and attached alternately to the needle in the vein. In the early stages of diphtheria the blood clots very rapidly in the damaged vein, so that the addition to the glucose of sodium citrate (grs. 5 to the ounce) is an advantage.

A NOTE ON SEPTIC CARRIERS.

BY LACHLAN GRANT, M.D., C.M., D.P.H. EDIN., F.R.F.P.S. GLASG.,

BACTERIOLOGIST, DISTRICT COMMITTEES ARGYLL COUNTY COUNCIL, CONSULTING MEDICAL OFFICER, BRITISH ALUMINIUM COMPANY, KINLOCHLEVEN.

A COMMON group of diseases with which medical practitioners have to deal is that of boils and local inflammatory and pustular skin infections, which occur more particularly on the fingers, hands, wrists,

forearms, back of the neck, and other skin areas, and at the nasal orifices. In other papers [1] I have fully discussed the probability that some of these troublesome and painful local infections result from the daily use of the present type of toilet and wash-hand lavatory basins. Most people wash their hands and faces several times daily in stationary water contained in the common unsterilised basins. They deposit in this water and on the walls of the basin the dust and dirt particles from the skin surfaces, which carry minute harmless or harmful "bacterial passengers." By the usual bacteriological methods these latter can be shown to be present in the polluted basins. It is thus plain that by washing in such a concentrated, contaminated fluid-medium, any micro-organisms present are applied and reapplied, again and again, to the washed (?) surfaces of the parts usually supposed to be correctly and properly cleansed. The result is that they are, to a large extent, deposited on the towels during the wiping and drying process. All this is surely quite unhygienic and insanitary. After such washings it is little wonder, whenever we get a wound of the skin, an abrasion, or an epilated hair leaving an open follicle, that staphylococcal, streptococcal or other pathogenic organisms frequently enter the open and exposed injured surface. These may then set up the complete infective and inflammatory process. At any rate, one must admit there is every possibility of this happening.

RECURRING BOILS.

Recently instances have been noted where several members of the same family suffered at intervals from recurring boils, or a too-ready inflammation of even simple wounds sustained in the course of the day's work, and it naturally occurred to me to go more fully into the medical history. In several instances an obvious origin for these inflammatory repetitions was soon apparent.

In the case of two patients from the same household, both of whom suffered within the past three years from numerous boils, several wrist infections—one of a severe type with abscess formation necessitating incision, following a transverse wound of the wrist—I found that the mother had a long-standing, chronic and open varicose ulcer of the lower leg, about 2½ in. by 3½ in. in size. In another male case with persistent periodic boils, it was discovered that the mother had a large, chronic, septic leg sore. These two poor and middle-aged women informed me they were quite distressed at their sons' frequent loss of work and wages through boils and abscesses which developed, in spite of repeated morning saline laxatives, a common method of prevention in many families. They did not realise that their own unhealthy integumentary systems were the likely carriers and distributors of the virulent organisms which caused these periodical infections; cultures from the chronic ulcers gave the usual staphylococcal growths.

In the treatment of these cases prophylactic aseptic daily cleansing by every member of the family was advised, and special mention was made of downward flushings from an elevated water tap. With one patient, in whose house no gravitation water-supply was laid on, the difficulty was overcome by washing at a nearby water spout—a natural running tap. Clean towels and garments were also recommended and, subject to careful local and general attention, with the occasional exhibition of a polyvalent staphylococcal vaccine, the boils and inflammations were cured, and for the past year there have been no recurrences. Meanwhile, with the aid of prolonged rest for the mothers, the op ulcers have responded to suitable treatment. ought to be of interest to state that the men affec were outdoor manual workers, liable to abrasions a other surface injuries.

HAND-BASIN CONTAMINATION.

This note is published with the suggestion t when these suppurative inflammatory infecti persistently recur, and where there is no syste condition such as glycosuria or a chronic furuncu state and where, in spite of pure water cleansin success is not achieved, it might be helpful to m fuller and tactful inquiries in order to discover there is not some carrier or harbourer of sep conditions in the home. Similar casual inflammat attacks in families may also result from the prese of septic teeth, chronic sinusitis, tonsillar infectio otitic abscesses, leucorrhœal discharges and fur cular conditions generally. It is obvious that from patients suffering from such diseases m daily enter the wash-hand basins, contaminat them and rendering them bacteriologically uncle Against infection from such sources the only effect precaution is to avoid washing in the station fluid, and to use pure running water for all the d ablutions. This can be easily carried out by us a combined elevated hot and cold water tap wit spray or single medium-sized jet inlet. Such mod and improved water faucets have already been f described by the writer in previous articles.[2] Tov can always be boiled, but the sterilisation of ev wash-hand basin after each usage is an absol impossibility.

Hence the necessity for the raised flow as a sim preventive remedy for these and other lar avoidable organismal infections. By the downw flush the dust and dirt particles, harbouring pathogenic bacteria, are carried off direct to waste and soil pipe. In this way there is no reappl tion of any infected microscopic suspended mat This method is so obviously correct that it se almost incredible that such faucets are not insta forthwith in every home and institution where gr tation water is laid on. Instead, the old-fashio primitive and dangerous toilet and lavatory bas with their close-up taps, are being used and fit for washing in the stationary water. This, as alre pointed out, favours the direct application of aggressive bacteria present, not only to the h cleansed skin areas but to the naso-oral orifice well. These microbic organisms, being "consi ately" rubbed in during the cleansing proce tend to inoculate the system, and any wounds abrasions of its cutaneous surface, with the poss risk of subsequently setting up one of the acute chronic, local or general infectious diseases.

GONORRHŒA IN THE FEMALE CHI

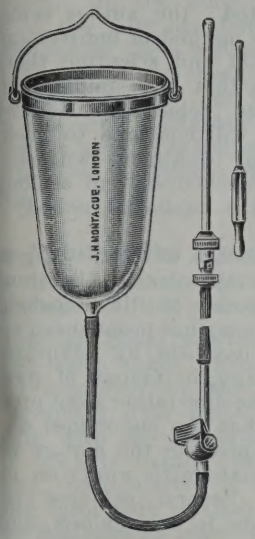
SOME POINTS IN TREATMENT.

By Harold G. Broadbridge, M.B., B.S. Lon
CLINICAL ASSISTANT, GENITO-URINARY DEPARTMENT, LONDON HOSPITAL.

In treating gonorrhœa in female children it difficult to obtain an even and thorough applica of a lotion or paint to the mucous membrane of

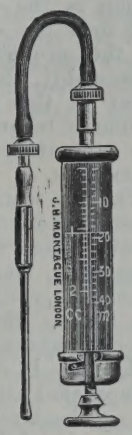
rethra and vagina, and I believe that quite a number f so-called relapses during treatment are due to ıadequate lavage of the mucosa with the antiseptic

FIG. 1.



Large cannula for vaginal douching. Small cannula for urethral irrigation.

FIG. 2.

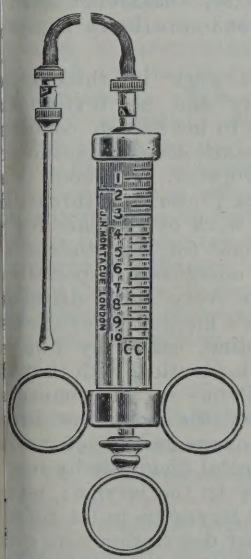


Urethral cannula and record syringe.

ı use. The cannulæ here illustrated were designed) facilitate thorough application of lotions, paints, nd the like to the child's urethra and vagina—articularly in gonococcal infections.

The urethral cannula is probe pointed at one end, while ıe other end receives a small nipple fitting. When in use 8 inches of narrow rubber tubing fitted with a male nipple connects the cannula with a stop-cock in the tubing of an ordinary irrigation jar (Fig. 1). The cannula is introduced into the urethra *with the lotion flowing*, and the stream is maintained while the cannula moves gently up and down the urethra. If it is desired to leave some of the lotion in the bladder to flush out the urethra when voided naturally later on (a method often used in adult women) it is only necessary to pass the cannula on into the bladder, the stream of lotion being continuous.

FIG. 3.



Vaginal cannula and syringe for pastes or viscid materials.

For paints such as solutions of silver nitrate a 1 c.cm. record syringe replaces the stop-cock in the rubber tubing (Fig. 2). In this case the unattached cannula is passed through the urethra until its probe point enters the bladder, as shown by the appearance of a few drops of urine at its other end. The cannula is then withdrawn into the urethra just sufficiently to prevent the escape of urine. The syringe, narrow tubing, and nipple are charged with the paint or application, and the nipple is attached to the annula, which is already in position. As the syringe is owly emptied the cannula is very gradually drawn along ıe urethra and out. The syringe must be filled with the arrow tubing attached, as otherwise the solution is simply xpelled into the empty rubber tubing and only air reaches ıe urethra.

The vaginal cannulæ are of two varieties: one with a ›ray nozzle for douching (Fig. 1), and the other with a ide-bore aperture for the introduction into the vaginal rnices of viscid materials—e.g., 2 per cent. flavine in ycerin (Fig. 3). This last cannula is connected with a 10 c.cm. syringe by narrow tubing fitted with nipples, the nipples in this case having bayonet catches.

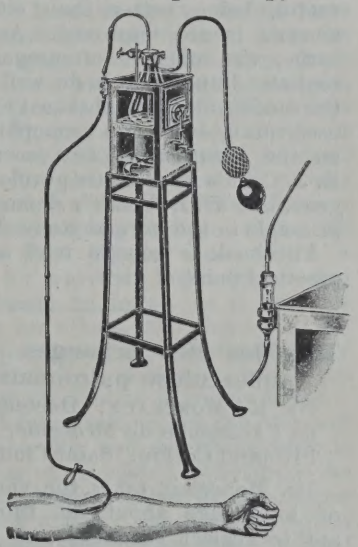
In using these instruments 8 inches of narrow tubing should intervene between the cannula and the supply of lotion. The introducing hand must rest firmly against the buttock. Should the child make any unexpected movement, cannula, narrow tubing, and hand of operator all move with the buttock, thus avoiding any risk of injury. The passage of these cannulæ into the urethra or vagina of a child causes little, if any, discomfort, and enables a complete antiseptic treatment to be given.

My thanks are due to Mr. Hugh Lett for allowing this work to be done in his department. The instruments are made by Mr. J. H. Montague, of 69, New Bond-street, London, W., and may be obtained singly or as a complete outfit.

NEW INVENTIONS

A PORTABLE THERMOSTAT FOR BLOOD TRANSFUSION.

THE apparatus here illustrated is on the principle of the Wassermann bath and its function is to keep the blood at the correct temperature throughout the operation of blood transfusion. The injection of blood at too low a temperature tends to produce pyrexial reaction and myocardial embarrassment, with undue post-transfusion sweating. Moreover, if the flask is immersed in a basin and kept warm by renewing the surrounding water, this operation becomes tiring to the nurses and inaccurate in its effects. The thermostat simplifies all this. The apparatus can be adjusted for any required temperature, but it is usual to work with it at 40–42° C. so as to allow a drop of 2° C. from the apparatus to the recipient. To summarise, the advantages are as follows. 1. One, if not two, assistants are dispensed with. The whole transfusion can be carried out unaided if necessary. In private work the apparatus is easily portable and invaluable. 2. The blood is guarded from disturbance. 3. It arrives at the patient at the right temperature constantly throughout the transfusion, however long. 4. Reactions become negligible, assuming that the cross test has been carried out properly; cardiac reactions are abolished, pyrexia is reduced to practically nil, whilst rigors become rare and of the mildest possible type, if present. For private work the oil burning type is recommended, but for institutional use the electric type is preferable.



The apparatus is supplied by Messrs. Charles Hearson and Co., of 27, Mortimer-street, London, W., and also by Messrs. Down Bros., St. Thomas's-street, London, S.E.

A. GEOFFREY SHERA, M.D., B.Chir.Camb.

REVIEWS AND NOTICES OF BOOKS

Liver in the Treatment of Pernicious and other Anæmias.

By S. C. DYKE, D.M. Oxf., M.R.C.P. Lond., Consulting Pathologist, The Royal Hospital, Wolverhampton. London: Jonathan Cape. 1930. Pp. 128. 5*s*.

THIS is a clear account of the liver treatment in blood diseases. After two concise chapters on the pathology of pernicious anæmia and the steps necessary for its diagnosis, a short history of the liver treatment is combined with a practical description of its details, including several recipes. In discussing liver extracts, the author points out that some of those on the market are useless, though others are potent. Other therapeutic agents such as hydrochloric acid and iron are discussed, and a preliminary transfusion is recommended for severe cases. Possible complications of the treatment are mentioned and the reticulocyte response is described. The methods suggested for an accurate reticulocyte count are somewhat cumbersome. Dr. Dyke clearly has no sympathy with the "toxic" theory of pernicious anæmia in any shape or form.

In secondary anæmia due to recurring hæmorrhage it is claimed that liver and iron together are definitely useful, being better than either alone. "Toxic" anæmia is not improved. According to Dr. Dyke sprue, the anæmia of pregnancy, and dibothriocephalus latus anæmia do well with liver; he quotes the successful results obtained by J. W. Pickering, who used this treatment in hæmophilia. The last chapter on the nature of the anti-anæmic principle describes E. J. Cohn's work on its purification so far as this has gone, and W. B. Castle's demonstration of the active principle in the normal stomach during digestion.

The book is easy to read and is written from a practical point of view.

Troubles des échanges nutritifs dans la tuberculose pulmonaire.

By R. MONCEAUX, Docteur-ès-Sciences, Lauréat de l'Académie de Médecine, Chef de Laboratoire à l'Hôpital Cochin. Saint-Cloud: Girault. Pp. 446.

Dr. Monceaux takes the view that in our pursuit of knowledge about the tubercle bacillus we are apt to neglect the study of the soil on which it grows. The 400 pages of his book are therefore devoted to an extensive study of metabolism as applied to tuberculosis, with little or no reference to the bacillus. Throughout the book the author chooses the physiological approach to the subject, and in many of his chapters gives an outline of the normal physiology of the organ under discussion.

The author divides the work into sections dealing with protein, fat, and carbohydrate metabolism, gaseous interchange and basal metabolism, the acid-base equilibrium of the blood, demineralisation and remineralisation, carotinæmia and liver function, whilst in the concluding sections he considers general questions of metabolism as they are affected by wasting in tuberculosis, by the results of open-air treatment, and by general hygiene. In the section on carotinæmia, a subject which is very little understood in relation to tuberculosis, or indeed to other diseases, Dr. Monceaux discusses the relation of the condition to cholesterinæmia and the failure of oxygenation. He does not give many quantitative analyses, but supplies adequate references. In the long section demineralisation and remineralisation many vie by many writers are quoted; the author sums by the statement that the method of indirect calc cation is the only rational and scientific thera but does not convince us that any simple soluti of the problem has been achieved. Meanwhi presumably, the clinician will continue to back fancy in the way of drug treatment without t serious a regard for the biochemist, and as long the laboratory findings are equivocal nobody c blame him.

The last section of the book is devoted to a gene consideration of the therapeutics of tuberculo viewed from the standpoint of the biochemi physician. Here Dr. Monceaux has pronounced viev which are contrary to those held by advocates the Gerson diet in Germany, in favour of pushi the carbohydrate side of the diet rather than prote and fats. It is a relief that the endocrines do r occupy that all-important place in the picture wh we are beginning to associate with works on me bolism in tuberculosis. Several coloured pla illustrate lesions of the liver in tuberculosis, and excellent bibliography is included; unfortunate no subject index is supplied. The book is full information, and in places both stimulating a provocative.

Diseases of the Nose, Throat, and Ear.

Medical and Surgical. Sixth edition. By WILLI LINCOLN BALLENGER, M.D., F.A.C.S., late Profes of Otology, Rhinology, and Laryngology, Univ sity of Illinois. Revised by HOWARD CHARI BALLENGER, M.D., F.A.C.S., Otolaryngologist the Evaston Hospital. London: Henry Kimpt 1930. Pp. 1138. 50*s*.

Prof. W. L. Ballenger's work in rhinology well known in this country and his text-book therefore of especial interest to his British colleag where it deals with the operations and methods treatment which he has elaborated. The book is of the larger works on the ear, nose, and throat, a is perhaps more useful as a work of reference for specialist than as a text-book for the student a general practitioner. The operations, especially rhinology and otology, are very fully discuss incidentally, Prof. Ballenger's method of enucleat the tonsils with the guillotine, called by him Ballenger-Sluder operation, is identical with that fi described by Whillis and Pybus in this country 1910. The weakest part of the book lies in description of the clinical appearances of vari diseases and in their differential diagnosis by insp tion. This applies especially to the larynx; no would recognise tuberculous laryngitis in its differ clinical aspects from the short description here giv and the single illustration gives a very poor idea the lesions usually found in this disease. The sa criticism applies even more forcibly to syphilis, this disease in the larynx is dismissed in just o one page and is not illustrated at all; altho syphilitic laryngitis is uncommon nowadays a kn ledge of the laryngoscopic appearances it present important in the differential diagnosis from ot affections. The much commoner syphilitic manife tions in the fauces are described very briefly in un two pages; all these affections are grouped un chronic granulomata of the nose, throat, and

one chapter in the section devoted to the nose and
cessory sinuses. Indeed, the larynx in general
ceives rather scanty notice, and the œsophagus even
ss, malignant disease of the gullet being discussed in
) lines. On the other hand, diseases of the ear
id of the nose are treated very thoroughly, the
erations on these regions being carefully described
id illustrated, and these sections of the book deserve
e highest praise. The proof-reading has not been
ry efficient; Krishaber's name is misspelt, a page
mastoidectomy is headed "simple thyroidectomy,"
id another on œdema of the uvula "edema of the
lva."

he Mind of the Savage.

By RAOUL ALLIER. Translated by FRED ROTHWELL
London: G. Bell and Sons, Ltd. Pp. 301. 15*s*.

MEDICAL men, administrators and missionaries
hose work takes them to those parts of the
orld inhabited by the simpler peoples ought to
e equipped with more than professional skill in
aling with the inhabitants of the country where
eir work is found. Some knowledge of anthro-
logy, particularly in its psychological aspects,
ould form part of their mental equipment. Prof.
lier has been for many years a student of primitive
e and mind, and attempts to supply in this book
e information necessary for appreciating the minds
savages or, as one ought to call them, simpler
oples. He follows very closely Levy Brühl and
e French school in the theory that there is a very
finite hiatus separating the civilised from the
vage. According to this school the savage mind is
e-eminently non-logical, or pre-logical; it takes
tle note of the law of contradiction and is little
le to remember new intellectual situations, although
possesses all the affective life and moral excellencies
ich civilised men have. Above all, the savage is
garded as overridden by magic, his life being
rrorised by the magical systems which hold his
nd in thrall. This conception is by no means
nerally accepted, and certainly English social
thropologists are not likely to endorse it. More-
er, in his very extensive studies of a subject calling
a knowledge of affective psychology, Prof. Allier
s entirely ignored Freud's work in general and his
rk on totem and taboo in particular. Roheim also
apparently unknown to him. Since these works do
empt to bridge the gap between savage and civilised
id neurotic), theories which take no account of
em are unsatisfying.

umeurs medullaires associées à un processus syringomyélique.

By Dr. N. JONESCO-SISESTI. From the Neurological Clinic of Prof. G. Guillain at the Salpêtrière. Paris: Masson et Cie. 1930. Pp. 295. Fr.45.

STUDENTS of neurology will welcome this fine
ntribution to our knowledge of a somewhat unusual
t well-recognised type of intramedullary tumour,
ich has its site almost always in the cervical or
rvicodorsal region. With this tumour is associated
secondary gliosis or gliomatosis extending up
d down the cord and, in its turn, exhibiting changes
ntical with those of syringomyelia as ordinarily
derstood. The monograph is based on five personal
ses, to which are added, for purposes of comparison,
e records of some 14 others obtained from the
erature. On the clinical side, sensory and motor
mptoms, irregular and asymmetrical, develop in
areas corresponding to cervicodorsal segments, the former leading the way in most instances, and exhibiting a syringomyelic dissociation during early stages. Later, large areas of sensory loss are manifested, and a spastic paraplegia below with atrophic palsies above. Lower cranial nerve symptoms are exceptionally rare, even though bulbar prolongation of the gliosis is found post mortem. Pathologically, the tumours belong to the class of fibroglioma or of ependymoglioma, with an occasional teratomatous formation; these are enveloped by gliomatous hyperplasia which proceeds to spread up and down, and in which syringomyelic cavities may subsequently appear. In the spinal fluid an "albumino-cytological dissociation" is usual. The author describes in some detail a case in which noteworthy clinical improvement followed radiotherapy.

The Spirit of Chemistry.

By ALEXANDER FINDLAY, Professor of Chemistry, University of Aberdeen. London: Longmans, Green and Co. 1930. Pp. 480. 10*s*. 6*d*.

THE quotation on the title page of this work defines the author's intention, which is to introduce chemistry to those who require instruction in the science as an element of general culture rather than as a part of their professional or technical training. The quotation runs: "It is not the particular facts of a science that constitute its vitality, but the generic facts or conceptions to which they have elevated the mind. Facts are the body of science, and the idea of those facts is its spirit." The words are those of Samuel Brown, a medical graduate of Edinburgh University, who failed to obtain the chair of chemistry in his alma mater because of certain strongly held but fallacious views, but whose literary works are well worth consulting to-day. Along the lines thus laid down Prof. Findlay has written a sound book and one for which an increasingly large number of readers should be found, as it becomes increasingly necessary for others than those who are destined for a scientific career to understand at any rate something of a branch of science on which the development of modern civilisation is largely based.

The introductory chapter, setting out the aim and methods of science generally, and describing what is termed the twilight age of chemistry, is not here the usual perfunctory introduction allied to the throat clearing of the nervous orator; the passages which refer us back to the classic learning are closely related to all that follows, and explain the brilliant theorising with which the subtle but practical Greeks sought to solve the riddle of the universe. In essential truths their teaching, or guessing, was right, and where it was wrong we see that the errors were largely due to lack of the material equipment possessed by the modern researcher. But their wisdom was hidden from the world throughout the dark ages, while what natural philosophy was manifest during mediævalism was perverted mischievously by mysticism. Especially is this true of the development of chemistry from alchemy. The critical move forward is attributed by Prof. Findlay to Robert Boyle, "the kindly, lovable, courteous, and humble-minded nobleman and man of science," whose life is coincident with the latter half of the seventeenth century. Boyle may be regarded as one of the founders of the Royal Society, for he was a member of the "Philosophical College," styled "invisible" because it had no home until it blossomed into "the Royal" under the patronage of Charles II. Boyle's "Sceptical Chymist" marked the

close of the alchemist's sway and the birth of chemistry proper.

The fundamental laws of that chemistry are so clearly expounded by Prof. Findlay that a sound conception of the science can be obtained by any educated person who reads these chapters closely, particularly if he has some elementary training in physics and is sufficiently industrious to work out the calculations for himself. Probably only at the expense of such interesting labour will the necessarily complicated terminology be easy of remembrance. An automatic familiarity with the fundamental precepts—the great general "laws," usually eponymous, of physics, chemistry, and electricity—is not easily obtained by those with whom its acquirement has not been part of an undergraduate's education. The terminology revolts such readers, who regard its novelty as an added difficulty to their studies, whereas technical terms are the price of exact thought.

The lessons to be drawn from an essay on the three states of matter—a most important section of the book—are brought into line with the latest views by chapters on radio-activity, atomic constitution, and the determination of the atomic weights. The chapters demand and will repay attentive reading, for as their facts and arguments are assimilated an understanding will be gained of the essential concepts of modern chemistry. The connexion appears between the work of Dalton and Mendeléef and Greek theorising, looking backwards, while, looking forwards, we see how the grand contribution from radiology confirms and infinitely expands the discoveries of earlier physicists and chemists. Thus scientific spirit will be created in the reader. Such a spirit is stimulated by the author's plan of writing, whereby the critical discoveries, which were followed by immediate progress, are placed in historical settings, portraits and biographical details being given of the protagonists. So the long story becomes continuous and absorbing.

Die Hypertoniekrankheiten.

Second edition. By Dr. ESKIL KYLIN, Director of a Department of the General Hospital, Jönköping. Berlin: Julius Springer. 1930. Pp. 270. M.22.

Dr. Kylin's main contribution to his subject is the distinction of two forms of hyperpiesis—namely, essential hypertension (hyperpiesia), which is determined by a primary disturbance of vasomotor control, and acute glomerulo-nephritis, which he visualises as primarily a disease of capillaries following and due to infection, and widely distributed throughout the whole body. Whereas essential hypertension is, in its initial stages at least, a functional disorder, and only later leads to structural change in the vessels, glomerulo-nephritis is at its first onset a widespread disease of capillaries to which arteriole spasm is secondary. In the former the capillary pressure is unchanged, whereas in the latter it is raised. The histological changes in the arterioles and capillaries in acute diffuse nephritis are described in long extracts from descriptive observations made by Huckel on two cases, in one of which death occurred 30 hours and in the other 2½ days after the onset of acute nephritis.

In support of his view that the disease is essentially an acute infection of capillaries all over the body, Dr. Kylin refers to cases under his own observation, and others reported in the literature, in which a rise of blood pressure occurs several days before there is any sign of nephritis on examination of the urine; he also speaks of cases in which, in addition to the rise of blood pressure, there is an increase of body-weight due to œdema with normal urine, and of the rathe doubtful cases of so-called acute nephritis, in which th whole course of the disease is run without albuminuria and finally he emphasises his standpoint by giving th name Capillaropathia acuta universalis to the diseas known as acute diffuse glomerulonephritis.

The introductory chapters on the physiology arterial and capillary blood pressure, the methods measuring these pressures, and their variations b day and during the passage of years, are well describe and the mechanism of hypertension is discussed i detail. The author is at pains to state the points o which he is in agreement or at variance with othe authors, and he particularly discusses the relation his views to those expressed by Prof. Volhard.

This monograph is written mainly from a theoretica point of view, and details of morbid anatomy an histology and of treatment of the diseases describe are somewhat slight. But it forms an interestin study of the relation of hyperpiesis to hyperpiesia acute and chronic nephritis, and chronic interstiti nephritis, and will be appreciated by those student of the subject who read German easily.

Les plexus choroïdes.

By Mme. Dr. NATHALIE ZAND. With a preface b Prof. Dr. G. ROUSSY. Paris: Masson et Ci 1930. Pp. 140. Fr.22.

Dr. Nathalie Zand's monograph on the choroi plexuses comes at the right time. Various theori of humoral-neural interaction, of neural infectio and defence, of nervous disease and nervous treatmen depend in part at least on the rôle played by meninge vascular endothelia; hence anatomical and physi logical prolegomena are indispensable. In th volume is succinctly set forth all that is known of thes subjects; the author summarises it in the significan conclusion (among others) that the cerebro-spina fluid is secreted by the choroid plexuses. She reject the view which considers the arachnoid a serou membrane of two layers, declaring for its unity; th epithelium over the plexuses, moreover, is held t differ morphologically and physiologically from tha of the ependymal cavities. In the connective tissu layers of the plexuses are arachnoid cells regarded b some as meningoblasts or meningocytes; Dr. Zan argues for their histiocytic nature, and assigns the to the reticulo-endothelial system with the functio of ensuring absolute protection for the nervou system from substances dissolved in the blood. Th latter third of the book deals at some length with th pathology of the plexuses, distinguishing acute an chronic lesions, and discussing changes in senility in psychosis, and in the more ordinary disease conditions of neurology.

A good bibliography is appended and there are number of illustrations, but the book lacks an inde

---

SHEFFIELD ROYAL INFIRMARY.—A new casualt block at this hospital, which has cost £23,000, wa unofficially opened last week. The building includes dermatological department.

NEWCASTLE-ON-TYNE CITY MENTAL HOSPITAL.— Last year there was a steady increase in the number patients of both sexes, and on one day in December la there were 1002 on the books, the largest number on recor The annual report of Dr. H. D. MacPhail, the medic superintendent, states that, although the general health the patients was good, the number requiring continuou treatment in bed increased out of all proportion to the increas in the number of patients. Deaths numbered 71, a lo rate compared with those of the preceding five years. Th average daily number of patients was 996.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 13, 1930.

DIET AND GROWTH.

INTEREST in the best means of promoting the physical development of children was renewed in this country a few years ago by the investigations of H. C. CORRY MANN, who showed that an additional daily allowance of a pint of milk considerably increased the rate of growth of boys. By control experiments he showed that this enhanced rate of growth was not due to the correction of any absolute deficiency either in the total energy value of the diet or in the magnitude of its protein, carbohydrate, or fat content. The Scottish Board of Health later repeated the work and obtained very similar results; at the same time they observed that skim milk had almost the same stimulating effect on growth as whole milk. This observation apparently ruled out the possibility that the fat-soluble vitamins of milk might be concerned with the phenomenon, for skim milk has been proved to contain negligible quantities of these substances. It is possible to speculate concerning the nature of the factor or factors present in milk which bring about the increased rate of growth, and to suggest for instance that it may be the peculiar quality of the proteins, the mineral content, or some hitherto unrecognised water-soluble accessory factor; but no opinion about this can yet be expressed with confidence.

There is another method of investigation which might throw light on the nature of the common dietetic deficiency in childhood which can be corrected by a supplement of milk—namely, the method of statistical survey. Such a survey is reported by Dr. J. B. ORR and Miss M. L. CLARK in the present issue, and it is useful to compare its results with those they obtained by direct experimentation during their study of the effect of milk supplements on growth. The present survey consisted essentially of a careful record of the amount of food entering the homes of a series of Scottish families during the period of one week. Corrections were made to the figures thus obtained for probable wastage, and by the use of standard food tables it was then possible to gain some knowledge of the average total energy value and of the average quantity of protein, carbohydrate, fat, and mineral elements in the daily diet of the individuals concerned. The data thus collected indicated that according to recognised nutritional standards there was no widespread deficiency either in the total amount of food eaten or in the protein, carbohydrate, and fat contents of the diet. The mean daily consumption of calcium and phosphorus was above the figure put forward by H. C. SHERMAN as representing a safe allowance for maintenance, whereas that of iron was a little below SHERMAN'S corresponding figure. In so far as these diets are compared with accepted maintenance standards they appear to be adequate on the whole, though in some towns, and especially Dundee, a large percentage of the families investigated consumed less than the standard amounts both of protein and of mineral elements. It is commonly recognised, however, that the needs of growing children for individual foodstuffs may be greater than that of adults. When allowance is made for this fact in handling the data collected in this survey it seems probable that a significant proportion of the children whose diets were analysed were getting too little protein, calcium, phosphorus, and iron to permit of their optimum rate of growth. If this is true, at least a partial explanation of the stimulating effect of milk supplements on the growth of such children might be forthcoming, for milk is acknowledged to be a particularly valuable source of good protein and of calcium and phosphorus, though its iron content is insignificant. It may be remembered that CORRY MANN found little stimulating effect on growth as the result of giving protein derived from milk as a supplement to boys' ordinary diets. This observation does not necessarily rule out the possibility that a lack of good protein plays a part in the sub-optimal rate of growth of Scottish children. The proteins in the basal diets of the particular English boys studied might differ in growth-promoting capacity from those in the Scottish children's; moreover, the proteins of untreated fresh milk may be capable of stimulating growth more effectively than those obtained from milk by a precipitation process.

It is not claimed that this nutritional survey has afforded any new information on the chemical constitution of the diets best suited to promote growth in children. It does, however, tend to support the conclusions reached by CORRY MANN, and confirmed by the Scottish Board of Health, concerning the value of milk for growing children.

VISCERAL DECOMPRESSION.

Sir WILLIAM WHEELER in his address at Winnipeg on the significance of recoil following visceral decompression, an abstract of which appeared on p. 541 of our last issue, drew attention to a principle of the greatest importance to clinical medicine. Sudden increases in pressure, whether acting on the body as a whole or on any separate organ or system, are catastrophic in their results; if produced gradually they give rise to some of the most beautiful adaptations of which nature is capable; if maintained too long or increased unduly, adaptation fails and catastrophe follows, no less disastrous because it has been delayed. Conversely the sudden release of pressure of any degree may give rise to effects as unpleasant as those of pressure. It is seldom possible to relieve pressure as slowly as it has arisen, but Sir WILLIAM points to many instances where our methods of relief might be better graded with advantage to the patient. One of the most dramatic instances of the need for a gradual reduction of pressure,

which does not come within Sir WILLIAM'S survey, is that afforded by caisson disease; others are the tense bladder of urinary obstruction and the distended bowel in chronic intestinal obstruction. Sir WILLIAM shows how the principle to which he has drawn attention applies to regions as diverse as the bowel, the liver, the urinary system, the spinal cord, and the eye; and while he does not discuss in any detail its application in the field of pure medicine, there are many obvious instances of its importance. In these times when the outlook of the general clinician is apt to be obscured by a wealth of important but sometimes bewildering laboratory detail, it is well to have his attention directed to certain broad general principles of physiology or pathology; such a survey, too, cannot but help the specialist to adjust the perspective of his own subject.

While Sir WILLIAM WHEELER'S thesis is no new one, it has a particular value in his collection of instances of a pathological process acting in much the same way on whichever system or organ it affects, and in his insistence that treatment to be efficient must recognise the state which it aims to combat, and must be based on a general principle rather than on details of technique. Back-pressure, however produced, is one of the primary pathological states to which the body is subject, and whether it affects organs grossly or in more local degree, the principle still holds that the greater the tension the more gradual must be its relief. There can be little doubt that many of our present-day procedures for the relief of back-pressure are too rapid in their action and this is perhaps particularly true of operations for intestinal obstruction. The practice of emptying distended coils as rapidly as possible, by means of a tube passed along the bowel from an incision in it, is dangerous in direct proportion to its efficiency, and as Sir WILLIAM points out the cases of obstruction that do best are those in which a slow steady drain can be established through a small tube. Perhaps nowhere else is the danger so well seen as in pleural empyema, where the risks of acute pulmonary œdema or of flapping mediastinum have gradually taught the lesson of slow relief; in children especially, repeated slow aspiration is necessary before drainage if fatality is to be avoided. Instances of the importance of the effects of recoil following visceral decompression could be adduced whatever organ of the body is being considered, and we feel that Sir WILLIAM WHEELER is to be congratulated on having used his large clinical experience to illustrate a general principle of wide scope.

PHRENICOTOMY FOR PULMONARY TUBERCULOSIS.

IT might be an exaggeration to say that there is a stage in every case of pulmonary tuberculosis at which treatment by artificial pneumothorax would be curative, but it is certain at least that this treatment remains the method of choice for most cases diagnosed when the disease is still limited in area and confined to one lung. If complete deflation of the affected organ can be secured the is a reasonable prospect of cure. Treatment mus however, be commenced before adhesions ha formed over the affected area and at a time whe the lung is free to collapse. If the pleura is n free localised adhesions are drawn out as the lur retires from the chest wall. The resulting strin or bands maintain the patency of cavities whic continue to act as incubators for the tubero bacillus. Thus, though the unaffected portio of the lung, if well contracted, may be free fro further danger, the integrity of the opposite lur is constantly threatened. If the bands are suitab for division by electrical methods effective collap may still be maintained. If their extent or situatio renders this impracticable, two further method of treatment are available: the major operatio of thoracoplasty or the minor operation of phren exairesis. The former imposes a severe psych logical and physical strain, may be followed b acute suffering, and is not without risk to lif The latter, carried out under local anæsthesi exposes the patient to negligible risks and mak no demands on his fortitude of mind or physic resistance. Section of the phrenic nerve was fir proposed by E. STUERTZ, in 1911, for tuberculosis one lower lobe. Disappointing results were obtaine however, by those who first practised nerve sectio Accessory fibres, especially those arising from th fifth cervical nerve, provided collateral transmissio of impulses and consequently in many cases th hemi-diaphragmatic paralysis was only temporar In the modern operation an attempt is made t withdraw the whole nerve and if ten centimetr can be secured a permanent paralysis results.

The chronic fibroid type of pulmonary tube culosis common in middle life is seldom seen in i early stages. The middle-aged working man pay little attention to a cough which causes but sligh disability in the winter months and scarcel troubles him at all in the summer. It is only whe increasing lassitude, severity of cough, or hæmo rhage interfere with his working capacity that h begins to suspect anything more than bronchiti When at last he reaches th esanatorium, possibl half of one lung is densely fibrotic and excavate in its upper lobe, and though physical signs may b unilateral the radiogram will show very definit involvement of the opposite lung. Cases of thi type are unsuitable for artificial pneumothora treatment, and as a rule the patient has neithe time nor patience for it. Thoracoplasty is still les applicable. A period of residence in a sanatoriu teaches the patient how to take care of himself an how to avoid infecting others; there is some gain i weight, and cough and expectoration are lessene On his discharge to his home a relapse is almos inevitable and death ensues within a few year It is in cases of this type that phrenic avulsion ma give very good results. Dr. R. W. MATSON ha reported an excellent series,[1] and his article demand careful attention.

Dr. MATSON has obtained his best results in th proliferative or fibrotic type of disease. He consider

[1] Amer. Rev. of Tuberculosis, 1930, xxii., 1.

hat in this type the capacity for collapse of the liseased areas of the lung is greater than that of the naffected parts. Consequently, though the upper obe is usually mainly affected, reduction in volume f the hemithorax enables the collapse capacity f the diseased lobe to exert itself. It is this collapse f diseased tissue, and not diaphragmatic stasis, vhich achieves benefit. The results of operation ave been striking. Dr. MATSON quotes a series of 4 cases of the productive type of disease affecting he upper lobe. In each case artificial pneumo-horax had failed and thoracoplasty was contra-ndicated by the condition of the less affected ng. In 52 per cent. of the cases the improvement following operation justified the hope of ultimate recovery. Tubercle bacilli were abolished from the sputum and the patients were able to return to work. In 38 per cent. there was definite improvement, but little prospect of permanent arrest. Dr. MATSON adduces further evidence in support of the modern teaching that phrenic avulsion should always precede thoracoplasty. He quotes a series of 32 cases of unilateral disease in which thoracoplasty seemed indicated. After phrenicotomy the number was reduced to 21. At the Winnipeg discussion (reported on p. 603) Dr. W. L. MANN also insisted on phrenic avulsion as a preliminary to thoracoplasty.

ANNOTATIONS

DEATHS FROM DIPHTHERIA.

ARE we making the best use of our knowledge of iphtheria? The question arises on perusal of the nnual reports of medical officers of health, and it efinitely gets the answer "No." Patients are far o often moribund on admission to hospital, and metimes their condition is directly attributable to elay caused by waiting for the result of a swab xamination. Such delay is obviously dangerous, r it is generally agreed that the efficacy of antitoxin iminishes rapidly until the fourth day of the illness, fter which it is almost valueless. It may be of terest to quote some of the opinions expressed in ne reports of medical officers for 1929. The Plymouth eport says there is much misconception about he value of swab examinations: it should be realised nat a negative report does not exclude diphtheria, and nat a positive only serves to confirm the clinical iagnosis. Every year patients are being admitted t a hopelessly advanced stage, and to prevent this is necessary that the antitoxin should be given first nd the swab taken afterwards. From West Ham omes the statement that the present practice of wabbing all suspected throats has not resulted in ny improvement in prevalence or fatality; that it now a firmly established practice to swab and wait r the result of the examination before giving anti-oxin; and that results would be better if practitioners lied upon their clinical diagnosis alone. By way of ustration a case is recorded, in which a practitioner, is said, saw a suspicious throat on a Tuesday, took swab, received a negative report on Wednesday, and ecided it was unnecessary to revisit. On Friday he as sent for and found the whole of the fauces covered ith membrane. The child was admitted to hospital nd died three days later. The Croydon report entions that of 21 diphtheria deaths in hospital x occurred within a few hours of admission. It claimed that the giving of antitoxin as soon as a se is seen at home would reduce the mortality, and is pointed out that severe and even fatal cases have ot very infrequently given negative swab results. he report from Tottenham urges that diphtheria ould be treated immediately upon clinical evidence nly. The delay in waiting to give antitoxin until ne receipt of the bacteriological result often turns ne scale against recovery.

Dr. E. H. R. Harries contributes to the Birmingham port some particulars of 69 cases which ended tally in the City Hospital in 1929. Nine patients ed within 24 and six more within 48 hours of admission; 24 were swabbed before admission; but only five had had antitoxin outside the hospitals, and three of these had it after the arrival of the swab report. The patients admitted for diphtheria numbered 2099, of whom 706 presented no clinical evidence and had the diagnosis revised. Of these 706, 368 had been swabbed and the diagnosis was apparently based on a positive report; the remaining 338 had not been swabbed. Among the 368 swabbed, 105 showed nothing abnormal, whilst of the 338 unswabbed, only 39 were free from pathological conditions. Dr. Harries's analysis also shows on what day of the illness the practitioner was called in. In 26 of the 69 cases this was after the fourth day. Thus parental delay is apt to increase the need of promptitude in administration of antitoxin.

TREATMENT OF DIABETIC COMA.

WHEN insulin was discovered it was supposed that any patient could be saved from dying directly from diabetes. But although the mortality from coma has greatly decreased, a certain proportion of cases still end fatally despite treatment which is deemed appropriate. Various workers have lately studied the causes of this failure. Lemann,[1] for instance, points out that alkalis are useless in coma and may even do harm. He thinks that insulin not only eliminates the ketone bodies by oxidation, but also reduces the acidosis by increasing the plasma bicarbonates. According to this view, whether the coma be due to the accumulation of ketone bodies in the blood or to the concomitant acidosis, insulin is the best treatment and he attributes most of his failures to too small a dosage. Lawrence [2] and Coburn,[3] however, find that insulin alone is insufficient, and the latter supports this thesis by the report of cases temporarily recovering from coma in pre-insulin days. While their main line of treatment is similar, these authors differ in their views on the main underlying condition. Lawrence considers that the intense polyuria consequent upon the hyperglycæmia results in the severe dehydration of the patient, as revealed by rapid feeble pulse, low blood pressure, empty veins, low ocular tension, and increased hæmoglobin and blood concentration; and that this is the main factor in the failure of the patient to recover from coma. The remedy he proposes is administration of large amounts of fluid intravenously

[1] Lemann, I. I.: Amer. Jour. Med. Sci., August, 1930, p. 266.
[2] Lawrence, R. D.: Brit. Med. Jour., April 12th, 1930.
[3] Coburn, A. F.: Amer. Jour. Med. Sci., August, 1930, p. 178.

and as soon as possible by mouth. Coburn, on the other hand, views the coma as due to the ketonæmia, the elimination of the ketone bodies in the urine being prevented by a functional renal insufficiency, and he quotes cases in coma with no ketonuria but with a large accumulation of ketone bodies in the blood. Again the treatment consists in the administration of fluid intravenously, which, in Coburn's opinion, acts by stimulating the excretion of ketone bodies in the urine. Whichever view proves correct, the obvious lesson of these observations is that all patients should receive large amounts of fluid intravenously, supplemented as soon as possible by fluid by mouth, and that adequate quantities of insulin and glucose should be given in addition.

A GUIDE TO OFFICIAL STATISTICS.

A GUIDE which covers the whole of the statistical information contained in official publications by Government departments of Great Britain and Northern Ireland is issued annually by H.M. Stationery Office (1s.). The eighth volume to appear has now reached us, and like its predecessors is a book of hardly more than 300 pages which retains its slender bulk by a well-planned system of cross references. An explanatory introduction, when once mastered, enables even one quite unversed in extracting statistical information to find not only which current official publications contain the figures he requires, but also to what mode of analysis they have been subjected. The bulk of the volume is devoted to a subject index which must be consulted with discretion if effective use is to be made of the guide. For example, the Registrar-General provides various statistics concerning each of 205 "causes of death." The inclusion of a direct reference to each is not attempted, for such elaboration would make the guide too bulky; for example, no reference occurs in the subject index to "appendicitis." But the subject "deaths" gives the number (620) of the official publication in which these statistics are recorded and its price. When once the principle has been grasped the professional man will have no difficulty in finding the technical details he requires. Under "Medical Research" the publications of the Medical Research Council and of the Ministry of Health are all indexed under their special titles, though some of them are scientific monographs which give little statistical information. This is a concession which will certainly be appreciated by medical readers, whose needs are moreover met in several other sections.

ACTIVITY OF VITAMIN D.

THE Council on Pharmacy and Chemistry of the American Medical Association have laid down a specification for the estimation of irradiated ergosterol in terms of good quality cod-liver oil by biological tests. In this standard the cod-liver oil may obviously vary greatly; and Holmes and Piggott,[1] in studying the antirachitic value of irradiated ergosterol 100 D (i.e., nominally with 100 times the vitamin D content of cod-liver oil), found that none of the samples had uniform antirachitic activity, and further, that the best sample only had 60 times the activity of the best cod-liver oil tested. The samples of cod-liver oil examined also varied greatly in their vitamin D content. These findings strongly support the action of the Medical Research Council who have recently issued [2] a new standard of vitamin D. The have chosen as their standard a preparation made b exposing pure ergosterol to ultra-violet light und carefully determined and measured conditions whic can be repeated at will. The estimation of vitamin in any material is to be performed by comparing i action with that of the standard in similar experiment animals under the same conditions. By this mea the variable factor, the experimental animal and i environment, should be obviated as much as possibl Hess, Poncher, Dale, and Klein[3] have attempted t determine the prophylactic and therapeutic dose irradiated ergosterol (viosterol) 100 D prepare according to the American specification. They foun that in children in the first year of life ten drops a da was the smallest dose that would prevent a fall in th calcium and phosphorus of the blood. No case on larger dose than this developed any signs of ricket Ten to 15 drops of viosterol daily produced healing i mild rickets, but more severe cases needed up t 30 drops a day. Although large amounts wer administered for six to eight months, no ill-effec were noted beyond constipation and colic. For time some of the infants received as much as 2 times the prophylactic dose, and the investigation held to show that there is "a large factor of safety i the administration of larger doses of viosterol least over limited periods."

DIATHERMY IN OTO-LARYNGOLOGY.

THE different forms of diathermy in use by laryng logists are clearly described in a recent monograp by Dr. Dan McKenzie,[4] and since electrical metho are becoming popular in this specialty it is wort while to master the rather confusing nomenclatur In medical diathermy a uniform heating is produce by two electrodes of similar size, while in "surgical diathermy a large passive electrode is employed ar a small active electrode which concentrates th current at the required point and so raises th temperature of the tissues sufficiently to produ coagulation. Two modifications of the surgic method are "fulguration" (the discharge produce when the electrode is brought near to, but not contact with, the tissues), which destroys the mo superficial layers by desiccation, and the "ar incision," in which the tissues are divided by th electric arc from a sharp fully-charged electrod Surgical diathermy is the method more general employed in the treatment of diseases of the throa and it is with this that Dr. McKenzie is chiefl concerned. For non-malignant affections there is n convincing evidence of its superiority to the old methods with knife or cautery. Dr. McKenzie h performed tonsillectomy by dissection both with th diathermy knife and with the arc. The former is th slower method but is less likely to cause hæmorrhag during the operation, but by neither method bleeding obviated during the stage of separation o the sloughs. He considers that, for this operatio diathermy presents no particular advantages over th ordinary dissection with ligature of the bleedin points; indeed, the usual dissection method woul seem to be preferable, for any considerable la hæmorrhage is an extremely rare sequela to th operation. For patients suffering from the results

[4] Diathermy, Medical and Surgical in Oto-Laryngology. I Dan McKenzie, M.D., F.R.C.S.E., Consulting Surgeon, Centr London Throat and Ear Hospital. London: Kegan Pa Trench, Trübner and Co. 1930. Pp. 184. 10s. 6d.

nsillar sepsis, when tonsillectomy is contra-indicated the general condition of health, Dr. McKenzie efers piecemeal diathermy to other methods, such the galvano-cautery or London paste; he coagutes one or more areas of about 1 cm. in diameter intervals of once a week or longer, and the duration treatment is from two to four months. It is knowledged that there is some soreness, the produre is a very tedious one, and it is at least difficult ensure the removal of the whole tonsil and nothing it the tonsil. The only really satisfactory method of eating diseased tonsils still seems to be complete rgical removal, and this operation is rarely contradicated by the patient's general condition if careful tention be paid to the method of anæsthesia. It is the treatment of cancer that diathermy in these gions finds its most useful application, and Dr. cKenzie gives a very valuable description of its plication both to "operable" and to ineradicable ncers. In connexion with medical diathermy the thusiastic French exponent of the method, Dr. obert Leroux, is quoted freely. The author's most portant personal experience deals with the treatent of deafness and tinnitus. Of 47 cases under care 5 were cured, but 4 of these had only ted for a few weeks, 5 showed great improvent, 13 improved but tended to relapse, in 2 the nitus increased, and in the remaining 22 there was change. Of 11 cases of less than one year's duran, 3 were cured, 4 improved, and 4 unchanged. these findings it is recommended that practiners should advise diathermy for patients suffering m deafness and tinnitus after colds and influenza, d after acute otitis. Conservative family doctors ay claim that older methods of treatment give st as good results in these recent affections. In y case there is no doubt that surgical diathermy s proved its value in laryngology, especially in the eatment of malignant disease, and this lucid expoion of the technique and results of its application ll be appreciated.

A TRAVELLING CLINIC.

SINCE 1924 the provincial department of health of tario has maintained a travelling clinic for the agnosis of diseases of the lungs. Clinics are ganised only with the consent of the county or al medical society or, where no such society exists, the practising physicians. Only one centre has en visited where this consent was refused. The ff of the clinic consists of from one to three ysicians and a nurse. The equipment includes a rtable radiological unit and X ray films are taken every case. Tuberculin intracutaneous tests are ne on all children under 16 years of age. No case admitted to the clinic unless referred by the family ysician, and no information is given to the patient the time of examination. When the clinic returns Toronto and the radiograms are interpreted and data are correlated, a typewritten report is sent the physician who has referred the case. This ort includes history, physical findings, X ray erpretation, a diagnosis if possible, and any ommendations that might be helpful. In this y the clinic is intended to work directly with the dical profession in the public service—a service ich is supplied by the department without cost to ysician or patient. The clinic will deal with any st case referred to it, including non-tuberculous ses, definite cases of tuberculosis, suspicious cases, d contacts. Especial importance is, however, ached to the examination of the two latter types of cases, especially where children who have been in contact with tuberculosis. Up to the present time 160 sessions have been held in 75 centres, upwards of 8000 cases having been examined. It is the intention of the department to establish some 20 centres in the Province in which clinics will be conducted once or twice a year as may be required.

HUMAN TRYPANOSOMIASIS TREATED WITH TRYPARSAMIDE.

IT is now eight years since the tryparsamide treatment of human trypanosomiasis was instituted in the Belgian Congo, and a critical analysis of available case records has now been made by Dr. Louise Pearce and published as Monograph 23 of The Rockefeller Institute for Medical Research. The total number of cases considered is 1848. Most of them were infected with *Trypanosoma gambiense* and were in an advanced stage of the disease; a small number were infected with *T. rhodesiense*. Dr. Pearce has maintained a judicious and conservative attitude towards the effect of treatment, based, as it should be, on the conception that a drug adapted to general use in African sleeping sickness must have a biological action likely to benefit patients in advanced as well as in early stages of infection. Tryparsamide is the sodium salt of N-phenyl-glycineamine-p-arsonic acid; the compound was developed at the Rockefeller Institute for Medical Research and was synthesised by Jacobs and Heidelberger, its biological action having been studied by Brown and Pearce. Though the arsenic content of the drug is high (25·32 per cent.) the dose that can be administered to laboratory animals by any route is very large; but there is a comparatively narrow margin between the lethal dose and the dose that produces no apparent organic impairment. While therapeutic tests on mice and rats may give a fairly accurate indication of potential trypanocidal action they convey little idea of the actual curative value. The infected rabbit is the animal of choice, since it shows many of the conditions, including involvement of the central nervous system, which are found in man. In this animal tryparsamide has proved highly effective especially in *T. gambiense* and *T. brucei* infections. A drug which will cure a well-developed infection in the rabbit in the same unit dose as will destroy parasites in the circulating blood must have great penetrating power, and it is to this power the therapeutic activity of tryparsamide is ascribed. In experimental animals the trypanocidal action of the drug has been found less potent against *T. rhodesiense* than against *T. gambiense*, and experience with human infections confirms this variation.

The first investigation on the action of tryparsamide in African sleeping sickness was carried out by Dr. Pearce herself in 1920. At its conclusion supplies of the drug were given to physicians in charge of the hospital at Léopoldville as well as to others in the Belgian Congo, and to those in charge of the Pasteur Institute in Brazzaville, in French Equatorial Africa. Further studies were afterwards made in the Cameroons, Angola, Nigeria, the Sudan, Uganda, and Tanganyika Territory. For the most part these reports are concerned primarily with the treatment of native patients in hospital "concentration camps." The greater part of this monograph concerns itself with an analysis of these extensive data, the number of European and American patients treated with tryparsamide being small. The work is carefully annotated and elaborate appendices are included. Its study will show that the drug has now an

established value. The Report of the League of Nations on the Second International Congress on Sleeping Sickness states that all medical officers agree that the former methods of treatment should be replaced by tryparsamide. The examination of the cerebro-spinal fluid and the institutional treatment of all cases presenting modifications of this fluid is advised. The course recommended is one of 12 injections, the maximum dose being 2 g. In the Memorandum submitted by the British Colonial Office to the League of Nations Conference, the Uganda report refers to the prophylactic value of injections of tryparsamide for members of any hunting party. Sterilisation of the blood was found to persist for a considerable period after such injection so that mechanical transmission from one individual to another and also the cyclical infection of the fly should be prevented by this means.

OCCLUSION OF THE CORONARY VESSELS.

IT is now 25 years since A. G. Fryett showed that the coronary arteries could be injected post mortem with a substance opaque to X rays, making it possible to study these vessels and their branches in detail and note the changes in disease. Since then several observers have worked on these lines with variations in technique and apparatus. In the September number of the *Practitioner* appears an important radiographic study of these arteries with special reference to coronary thrombosis by Dr. E. Wyn Jones, from the heart department of the Liverpool Royal Infirmary. It differs from previous work in combining clinical observation of individual cases with subsequent pathological investigation—a method that should be fruitful of results. Dr. Wyn Jones—whose article was adjudged to be the best submitted in a competition open to practitioners of not more than two years' standing—devised his own method of injection, on the lines of the standard technique introduced by Louis Guss in 1921 but simpler and easier of manipulation. His findings agree in the main with those of previous investigators, but he is able to add two new facts to our knowledge: one, that in 5 per cent. of hearts the left coronary artery is the sole supply of the neuromuscular tissue, the other that 11 per cent. of all hearts possess three coronaries, the accessory vessel being found more commonly on the right in the proportion of 8 : 1. Possibly the latter is the accessory vessel demonstrated by J. S. Campbell in 1927 at a meeting of the Association of Physicians of Great Britain and Ireland, and judged by him to be a branch arising from the right coronary artery near its origin; this vessel was present in 20 per cent. of his series.[1] Dr. Wyn Jones notes that the coronary anastomosis becomes much more extensive with increasing age, a fact confirmed by others, and it is of interest to realise that previous coronary disease is an advantage to the patient whose artery is occluded; the gradual diminution of the lumen of the vessel by atherosclerosis allows an efficient compensatory anastomosis to develop, so that when the final block occurs the new anastomotic channels are ready to take on the necessary work. Again a condition of high blood pressure is also an advantage to the patient, for the fall of pressure consequent on the shock of the sudden thrombosis is not so great as it would be in a patient if the pressure were normal, and there is no delay in the opening up of new anastomotic channels. This has been shown to be the case experimentally animals, where the lower the blood pressure the larg the infarcted area produced.

Each observer who has investigated by the methods has been able to add something to o knowledge of the coronary artery circulation, a how it is affected by disease. More particularly are learning something of the cause for the vari individual reactions to blockage of the same ves or the same branch of a vessel. W. Spalteho in 1907, by means of his injection and cleari technique, claimed to have demonstrated that end-arteries existed in the heart, and that there wa rich anastomosis in all its muscular and endothel layers. Gross established the fact with his rad opaque bismuth injection technique. "The heart" he said, "is perhaps the richest organ in the body regards capillary and precapillary anastomoses betwe branches of the same main vessel and between branch from the two sides." Gross also showed that t accumulation of epicardial fat added to the hea a vascular sheath which slowly thickened with a and made anastomotic communications with t underlying muscle, thereby putting a new complexi on the behaviour of epicardial fat which up till th had often been suspect of causing sudden dea where no other cause could be demonstrated. Final Geoffrey Hadfield confirmed [2] Gross's statement a was able to show that the anastomoses in the epicard fat of the senile heart helped it to compensate to considerable degree for a diminished flow throu its atherosclerotic vessels, provided there was serious drop in blood pressure. Using the celloid technique of Morison followed by erosion in stro acid, Hadfield confirmed the presence of innumeral anastomoses, which explained recovery followi extensive coronary occlusion. In the future it m prove possible to inject some substance opaque X rays into the veins of the living subject, permitti a detailed examination of the coronary circulati during life.

THE ORAL INJECTION OF LIPIODOL.

FOR introducing lipiodol into the lungs oral injecti seems to be the method of choice in America, and increasingly employed in this country. The ea with which it can be done is often almost incredib With no previous anæsthetisation, with the patie sitting on a chair and holding out his own tong and with apparatus no more elaborate than ordinary 20 c.cm. syringe and a straight cann the oil can be steadily dropped over the back of t tongue into the trachea, and the whole affair may over in three or four minutes. Many patients w declare themselves unaware that anything is happe ing, but others, of course, are intolerant. Othe again, while appearing to allow the oil to desce the trachea, will hold the oil above the glottis a then expel it all by a sudden cough. In such a ca it is an advantage to be able to see exactly where t oil is going, and Arnold Josefson, of Stockhol has described [3] an instrument for this purpo It consists of a curved spatula along the upper surfa of which is affixed a cannula projecting beyond t end of the spatula; above this is a lamp and laryngeal mirror. Such a device may be of value difficult cases, but with gentle persistence it will found that even the intolerant are often able to all the oil to flow down the trachea. Lipiodol injectio

[1] THE LANCET, 1926, ii., 168.

[2] Brit. Med. Chi. Jour., 1927, xliv., 257.

[3] Acta Med. Scand., 1930, lxxiii.,

e so important in diagnosis, and the oral method so simple and so infinitely more agreeable for the tient than the crico-thyroid route, and so free of l dangers, that every effort should be made to quire the technique. Some say it is impracticable d inferior to other methods, but this is not the rdict of more experienced workers. By suitable sture during and after injection, the oil may be ade to reach the very apices of the lungs by the oral ute, as was well shown in the paper by Dr. W. rton Wood which we published on June 21st . 1339). A full description of the method, which was rked out especially by J. J. Singer, of St. Louis, ay be found in a monograph on lipiodol in the agnosis of thoracic disease reviewed in our columns st year.[4]

HOSPITAL SWEEPSTAKES.

APPARENTLY the promotion of hospital sweepstakes likely to become a special line of business in the ish Free State. There is, in the first place, the veepstake being organised on the Manchester ovember Handicap by a committee representative six of the Dublin hospitals. This committee has en registered as "Hospitals' Trust, Ltd." It pears to intend to widen its scope in future, for is stated that a meeting was recently held, on the vitation of the hospitals concerned in the Trust, of presentatives of the boards of several hospitals roughout the Irish Free State, to arrange for a more neral participation in future sweepstakes. Reprentatives from institutions in Cork, Limerick, aterford, and Louth, as well as from several in ublin, were present, and tentative agreement was ached to organise a sweepstake on next year's rand National. Side by side with this enterprise, new private company was registered last week der the title "The Charities Guild, Ltd." with the ject of promoting sweepstakes and drawings of izes in aid of charitable institutions in the Irish ee State. The managing director is, according to e press, a "well-known turf accountant." The story of the first sweepstake will be watched with uch interest by those concerned with hospital ance. Whether sweepstakes are to become one the principal sources of revenue to Irish hospitals to sink into disuse will depend on two factors—mely, the amount of money subscribed, and the oportion of it that reaches them.

ŒDEMA DUE TO INANITION.

AT the end of the Great War the prevalence of lema, called "war œdema" or "famine œdema," tracted considerable attention in Central Europe, well as in other parts of the world. It was associated th a very poor diet, consisting almost entirely root vegetables, and various explanations of it were ven. Many observers referred it to the high salt ntent of the diet, but A. Schittenhelm and H. hlecht,[5] who studied the condition in prison camps, ncluded that it was best treated by rest and creased fat and protein in the diet. In 1920 A. Kohman,[6] who was investigating the dietary operties of carrots with rats, found that when the et consisted of little else a certain number of the ts upon it tended to develop œdema. Further vestigation seemed to inculpate the protein as the ly significant factor. Œdema in a monkey, fed on diet in which the only proteins were those derived from maize, was described by H. Chick and E. M. Hume[7]; the œdema was rapidly cured by administration of casein. After the war period the urgent practical interest in the problem died down, and it was left in an interesting but inconclusive position for nearly ten years. Last year R. A. Frisch, L. B. Mendel, and J. P. Peters[8] repeated and extended Kohman's work and have established that œdema is produced in rats on a diet in which the protein is entirely derived from carrots. The œdema is accompanied by a marked lowering of the serum proteins, which after two to three months are reduced by 40 per cent. When starch up to 18 per cent. of the total calories is withdrawn from the diet and replaced by casein, the œdema does not develop and the serum proteins are maintained. It is pointed out that E. H. Starling[9] first showed that the colloid osmotic pressure of the serum is proportional to the concentration of protein in it, and he advanced the theory that decreased osmotic pressure in the serum is responsible for the deposition of water in the tissues. Starling's suggestion was subsequently contested but the work just quoted substantiates it, besides affording confirmatory evidence of the dependence of war œdema upon a poor protein supply.

Not long ago Dr. F. J. Poynton and Dr. J. V. Macgregor described[10] in our columns a fatal case of gastro-jejuno-colic fistula in which œdema developed in consequence of deficient absorption, and two less serious cases have lately been reported at the Mayo Clinic by Dr. A. M. Snell.[11] Both Dr. Snell's patients were suffering from pyloric obstruction and had for some time been on inadequate diets, and both had required the administration of large quantities of fluid. The precipitating factor may have been the enforced abstinence from food after operation. Pitting œdema appeared in the legs of the first patient, a woman aged 61, fifteen days after excision of an ulcer and posterior gastro-enterostomy. Marked œdema developed a fortnight after the same operation in the second patient, a plumber aged 44. Investigation of the blood showed that at this time the serum proteins were about 30 per cent. below the normal level—i.e., about 5 g. per 100 c.cm. In both cases there was marked secondary anæmia, which may have interfered with the oxygenation of the tissues and reduced the permeability of the capillaries. The patients were given a diet of high vitamin content with an adequate supply of protein; the first had full doses of ferric citrate and rapidly improved until, at her discharge about six weeks later, the concentration of serum proteins was 7·7 g. in 100 c.cm. and the hæmoglobin and red blood-cell count were practically normal. The second patient had a transfusion of 500 c.cm. of blood, which caused moderate diuresis for two days. After this the œdema was greatly reduced and the serum proteins rose to 5·9 g. in 100 c.cm. Both patients made complete recoveries. These mild grades of inanition œdema must, Dr. Snell thinks, often escape recognition. Provided that the causative disease is not progressive and a high protein diet can be taken, treatment is very effective.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—At the provincial meeting of this society to be held at Lowestoft on Sept. 19th–20th, the members will be entertained by the Mayor and Corporation of Lowestoft at luncheon on the 20th and not on the 19th as stated in our previous notice.

MODERN TECHNIQUE IN TREATMENT

A Series of Special Articles, contributed by invitation.

CCCVI.

TREATMENT OF CASES OF ABORTION.

PART I.*

BLEEDING from the uterus is almost invariably a precursor of abortion, but there are many pregnancies in which there has been some bleeding that go to term. If bleeding occurs during pregnancy before the child is viable, it must be regarded as a threat of abortion, and it is impossible to say at the onset of the bleeding whether or not the pregnancy can be saved. If the bleeding is free, and there are uterine contractions, there is much greater risk of the pregnancy being destroyed than if there is only slight loss, but in many cases with a very small amount of bleeding the abortion ultimately becomes complete; again in some where the bleeding is extremely severe the pregnancy may continue. All cases of bleeding early in pregnancy must be treated as only threatened abortions until there are definite physical signs that abortion is inevitable, except when the bleeding is so severe as to be a danger to the woman's life. In many cases where abortion is threatened the woman is mentally disturbed and upset at the thought of losing her child, and this state of agitation seems to have an influence in increasing the activity of her uterus and so making an abortion more likely to occur. Any added worry or disturbance caused by anxious relatives or by examination of the patient increases the risk of making a threatened into an inevitable abortion.

In dealing with cases soon after the onset of bleeding, unless the loss is very profuse the patient should be put to bed with as little fuss as possible and given sedatives to reduce her anxiety and to diminish the activity of her uterine muscle. At this stage vaginal examination should be avoided, but if the pregnancy has reached the stage at which the uterus should be palpable a gentle examination of the lower abdomen should be made to make sure that the uterus is of reasonable size for the duration of the pregnancy. If the pregnancy is thought to be in the first two months or so it is wise to inspect the breasts and to make inquiries about symptoms to be sure if possible that the woman is actually pregnant. In the early part of the treatment of threatened abortion the type of sedative needed is one that acts powerfully and quickly, and for this purpose morphia is perhaps the most certain and convenient, but heroin and omnopon are good and may be used in place of morphia. At the onset of the bleeding, after ascertaining the amount of loss and satisfying myself that there is no reason to suspect extra-uterine pregnancy, I give an injection of morphia gr. $\frac{1}{4}$, and if after a few hours the bleeding shows signs of stopping I give 30 grains of bromide and order a mixture containing 20 grains to be given three times a day. If all loss of fresh blood has ceased after three or four days the bromide can be discontinued, but the patient should be kept in bed at least a week from the time the discharge has ceased to be red. If the bleeding does not stop or obviously diminish in six or eight hours after the morphia has been given, another injection may be tried, and if this fails a vaginal examination must be made as already signs that the abortion is inevitable may be present and further attempts to save th pregnancy are useless.

Inevitable Abortion.

Abortion is inevitable if any part of the ovum can b felt at the external os; when this is possible it mean that the cervix has been taken up and the ovum is i process of extrusion. It is often difficult to be quit certain that what is felt at the external os is part o the ovum and not clot, and to satisfy oneself that th cervix is taken up, especially in a multipara with damaged cervix. When the amniotic sac is presentin and felt there is no great difficulty in recognising it but clot and a mass of chorion may easily be mistake for one another, and as too thorough an examinatio may do harm it is better to wait and assume tha what is felt is only clot and to carry on treatment fo threatened abortion. If any part of the decidua o the ovum has come away abortion is certain to occu but is then classified as an incomplete and not as a inevitable abortion. Perhaps the part of the ovu that can be expelled most easily without attractin notice is the amniotic fluid, but if this has escape there is no hope of the pregnancy continuing.

When the abortion is inevitable or incomplete ther is nothing to be gained by delay in its completion an the sooner the uterus is empty the better. In th absence of bleeding reasonable time should be allowe for the uterus to empty itself naturally, and this i especially important if the pregnancy has gone as fa as the fourth month, because at or after this tim evacuation of the uterus may be extremely difficul and dangerous until the cervix has dilated enough t allow the head to pass through it. Usually th progress of labour in inevitable or incomplete abortion is fairly quick, and within 10 or 12 hours th uterus empties itself; so that all that is needed is t keep the woman in bed under observation in cas there should be bad bleeding while the abortion is i progress. Fortunately, the later the pregnancy th more likely is the uterus to expel its contents, so tha it is not very common to have to resort to surgica evacuation after about the fourth month. In suc cases, if there is delay and the os is only slightl dilated, it is best to deal with the case as with a labour a term and wait for natural delivery, unless interferenc is necessitated by severe bleeding; when this occur rupture of the membranes may hasten delivery, o packing the vagina may be needed to stop th hæmorrhage and cause dilatation of the os by stimu lating the activity of the uterus.

In abortions occurring in the first three months if after 10 or 12 hours the uterus is not emptying itself, drugs to stimulate uterine activity should b tried; a drachm of liquid extract of ergot, 1 c.cm. o 10 per cent. pituitary extract, or a drachm of one o the newer preparations of ergot such as ernutin may be given, and half these doses repeated three or fou times in the next 24 hours. If after this the ovum is not expelled, the probabilities are that it wil be retained for a considerable time, and it is bette to evacute the uterus than to wait longer. Until th uterus is empty there is always some risk of free o even dangerous bleeding occurring, so when th likelihood of early natural expulsion has become smal this risk should be avoided by completing the abortion There is also some risk of infection of the retaine products, which is reduced by removing them. The early ovum in cases of inevitable or incomplet

* Part II. will appear next week.

abortion is usually very easily removed, as it is often lying in the lower segment of the uterus and detached or only adherent over a small area.

Removal of the Early Ovum.

The patient should be anæsthetised and prepared for a vaginal operation and the vagina swabbed out thoroughly with 1 in 2000 perchloride or biniodide of mercury solution. The cervix is then drawn down and painted with 2 per cent. iodine. Frequently the cervical canal will admit the finger, and if so the presenting ovum should be detached and removed by the finger and ovum forceps. If the finger cannot be passed through the canal the cervix should be dilated with metal dilators until this is possible; after removing the ovum the cavity of the uterus should be explored to make certain that it is empty, and any fragments found should be removed by the finger or the blunt curette and the cavity swabbed out with a strong antiseptic. The antiseptic I am in the habit of using is a spirit solution containing grs. 75 of iodine and grs. 96 of potassium iodide to the ounce. It is important to remember in exploring the cavity for fragments of ovum that the placental site is rough and somewhat raised, and may feel not unlike a retained piece of ovum, and also that the wall of the uterus is soft and may be perforated by too vigorous attempts to remove retained fragments even with the blunt curette. After an abortion, whether terminated naturally or not, the patient should be kept in bed at least one week, and if the pregnancy had reached four months it is better not to allow the patient up in less than ten days.

Retained Products.

After a threatened abortion has been treated with apparent success, it is not quite certain that the pregnancy has been saved, because the ovum may have died at the time of the bleeding and be retained in the uterus for a considerable time without causing further bleeding. A woman who has had bleeding during a pregnancy should be seen a few weeks later to make sure that the uterus is increasing in size and the breasts developing in the ordinary way. If there is any doubt of the ovum being alive it may be necessary to wait another month before a definite diagnosis of retained dead ovum or carneous mole can be made, and then if there is no sign of its being expelled by the uterus, the cervix should be dilated and the retained ovum removed in the same way as in the case of inevitable abortion. If there is bleeding or brown discharge ergot should be given a trial before dilating the cervix.

J. P. HEDLEY, F.R.C.S. Eng.,
Obstetric Physician to St. Thomas's Hospital.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdrs. C. V. Griffiths to *Victory* for R.N. Hospital, Haslar; O. D. Brownfield to *Dorsetshire*; and J. H. Burdett to *Pembroke* for R.N. Hospital, Chatham.

Surg. Lt.-Comdr. A. de B. Joyce to *Victory*, additional for R.N. Hospital, Haslar.

Surg. Lts. J. C. Souter to *Tarantula* and A. M. Lawrence-Smith to *Cicala*.

Surg. Lts. A. L. Moorby and E. R. P. Williams are transferred to Permanent List.

ROYAL NAVAL RESERVE.

Surg. Lt. A. Elliott to *Vivid*, for R.N. Barracks.

Surg. Sub.-Lts. A. R. Hunt promoted to Surg. Lt., and A. D. Lendrum to *Victory* for R.N. Hospital, Haslar.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. A. L. Gunn to *Victory* for R.N. Hospital, Haslar.

Surg. Sub.-Lt. R. J. Davies to *Vivid* for R.N. Barracks.

Proby. Surg. Sub.-Lt. L. A. De Dombal to be Surg. Sub.-Lt.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. R. J. Franklin retires on ret. pay.

The undermentioned Majs. (temp. Lt.-Cols.) to be Lt.-Cols.: C. Scaife, vice Lt.-Col. R. J. Franklin, to ret. pay; E. B. Lathbury, vice Lt.-Col. R. C. Wilmot, promoted.

The undermentioned Majs. to be temp. Lt.-Cols.: E. D. Caddell and B. Johnson.

Maj. R. I. Sullivan, from the secd. list, is restd. to the estabt.

ARMY DENTAL CORPS.

Lt. G. T. Drummond, temp. Dental Surg., to be Lt. (on prob.).

TERRITORIAL ARMY.

Lt. C. C. Taffs is restd. to the estabt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

R. H. Franklin (late Lt., R.A., T.A.) to be Lt.

ROYAL AIR FORCE.

RESERVE OF AIR FORCE OFFICERS.

Flying Officer F. G. Mogg, of the Special Reserve, is promoted to the rank of Flight-Lt.

INDIAN MEDICAL SERVICE.

Majs. to be Lt.-Cols: J. Scott, F. W. Hay, S. M. Hepworth, H. S. Cormack, K. G. Pandalai, J. L. Sen, C. A. Wood, P. B. Bharucha, and L. H. Khan.

The undermentioned appts. are made: D. J. Young and P. L. O'Neill to be Lts. (on prob.).

The undermentioned officers retire: Lt.-Cols. J. McC. A. Macmillan and T. C. McC. Young.

Lt. V. H. Sarland resigns his commn.

INDIAN MEDICAL DEPARTMENT.

Sen. Asst. Surgs. and Lts. to be Senr. Asst. Surgs. and Capts: A. Bayley-de Castro and R. H. G. Thompson.

First Class Asst. Surgs. to be Senr. Asst Surgs. with rank of Lt.: A. D. Campbell (secd.) and J. G. Johnstone.

Senr. Asst. Surg. and Maj. T. W. Twells retires.

NORTH PERSIAN FORCES MEMORIAL MEDAL.

Captain H. W. Mulligan, M.B., Indian Medical Service, has been awarded the North Persian Forces Memorial Medal for the year 1929 for his paper, Studies on the Reticulo-endothelial System, with Special Reference to Malaria, published in the *Indian Journal of Medical Research* (1929, xvi., 1099). This medal is awarded annually for the best paper on tropical medicine or hygiene published during the preceding 12 months by a medical officer, of under 12 years' service, of the Royal Navy, Royal Army Medical Corps, Royal Air Force, Indian Medical Service, or of the Colonial Medical Service.

A COURSE OF PSYCHOLOGICAL MEDICINE FOR THE PRACTITIONER.—Twenty-four lectures on Psychological Types and Mechanisms will be given at the Tavistock-square Clinic for Functional Nervous Disorders, 51, Tavistock-square, London, W.C. 1, on Wednesdays, beginning Oct. 1st. Dr. E. Graham Howe will lecture from 3 to 4 P.M. every week, the subjects being:—Nerves: Physical and Mental Disorder contrasted; the Neurological and Analytical Viewpoints; Causes of Mental Disorder.—Dynamic Psychology and the Conception of Purpose: Conscious and Unconscious Conflict; Repression; Rationalisation.—The Way the Mind Works: Symbolism, Dreams, and Symptoms.—Emotional Development: (*a*) Racial Factors; (*b*) Individual Factors.—Law: the Rôle of the Father.—Love: the Rôle of the Mother.—Sexual Contrasts: Sadism and Masochism.—Adaptation: Fear; Guilt; Inferiority; Over-compensation.—Wish Fulfilment: Projection.—Resistance and the Unconscious Motive.—A Conception of Mental Disorder: Good and Bad Adjustment. Dr. H. Crichton-Miller will lecture from 4.30 to 5.30 P.M. on Introversion and Extraversion.—Thinking and Feeling Types.—Intuitive and Sensorial Types.—Aggression and Surrender: Sadism and Masochism.—Art and the Creative Type.—Compulsions and the Repetitive Type.—Epilepsy and Psychasthenia.—Neurasthenia and Vagotonia.—Anxiety and Sympathicotonia.—Hysteria and the Ovarian Type.—Dementia Præcox and the Schizoid Type.—Manic Depression and the Cycloid Type. The lectures are open to the medical profession only. Tickets for the course can be obtained in advance from the Hon. Lecture Secretary at the Clinic.

SPECIAL ARTICLES

A DIETARY SURVEY

OF SIX HUNDRED AND SEVEN FAMILIES IN SEVEN CITIES AND TOWNS IN SCOTLAND.*

BY J. B. ORR, *D.S.O.*, *M.C.*, M.D., D.SC. GLASG.,
DIRECTOR OF THE ROWETT RESEARCH INSTITUTE;
AND
M. L. CLARK, L.L.A.
(*From the Rowett Research Institute, Aberdeen.*)

IN the course of the investigation already reported in THE LANCET [1] on the effect of feeding milk to school-children, information on the dietaries of the homes of a number of the children was collected by Dr. K. Rounsfell Brown, Dr. A. F. Turner, Dr. E. M. Henderson, and Dr. H. M. Morrison in the winter and spring of 1926–27. The collected data have since been analysed by Miss Clark who has drawn up and arranged in convenient form the information, including the tables, given in the present report.

Methods of Investigation.

COLLECTION OF INFORMATION.

For the collection of the information, printed forms with sections for each class of common food, with a space for additional foodstuffs, were used. To minimise the risk of items being omitted, the enumeration of the foods in common use was fairly extensive. One of these forms was used for each household. A note was taken of the composition of the family, and a record was made of the food consumed for the period of a week. In some families occasional meals, as for example dinners at schools or soup kitchens, were taken outside the home. Information with regard to the nature of these was obtained and the necessary additions made in calculating the total food consumption of the family. The investigators attempted, by personal observation or by comparing the statements made on consecutive visits, to check the accuracy of the information supplied by the housewife. A thorough and effective check of food consumption was, of course, obviously impossible. It should be noted, therefore, that the basal data consist essentially of statements of the housewife, and not of direct observations of the investigators.

In each case the investigator made a note as to the reliability of the information received. All cases which were regarded as being unreliable were rejected. In addition, some sheets, though regarded by the investigator who collected the information as being reliable, were rejected because internal evidence showed a probability of errors or omissions. In all, 700 sheets were completed. After throwing out unreliable cases there were left 607 which, so far as is known, give a relatively accurate account of the weekly consumption of food in the households concerned.

This method of collecting information on the dietaries of households is obviously much less accura than the intensive methods used in studies suc as those made by Noel Paton and Cathcart, in whic the amount of food consumed was determine accurately in a small number of households. O the other hand, the present method, though le accurate for each household, enabled a wider fie to be covered by the workers in the time availabl While there may be some doubt as to the probab error of the quantities of foodstuffs consumed, it believed that the records of the kind of foodstuf used in the various households are fairly accurat and give an indication of the quality of the die It was thought that if the caloric intake as calculate from the data was found to be in agreement wit that obtained in the more intensive surveys, th information collected might be regarded as sufficient accurate to warrant drawing tentative conclusio as to the quality of the diets.

WORKING UP DATA.

Plimmer's tables [2] were used for the calculation the protein, fat, and carbohydrate content and th caloric value of the diets, and Sherman's [3] for th mineral content, except in the case of iron where th data of Peterson and Elvehjem [4] were used. F foods not given by these authors, data were obtaine in some cases in the Physiology Department Glasgow University or in the Rowett Institut In other cases where no data were available foodstuf were analysed. The consumption of some articl such as eggs, oranges, bananas, and vegetables w stated in quantities instead of weights. These we assessed on an average weight ascertained by tri at shops.

The percentage of inedible material in vegetable fruits, meat, and fish according to Plimmer's tables deducted. No allowance, however, is made for was or loss in cooking. The figures given in the tabl therefore, show the amount of edible material enteri the home and not the amount actually consume The Food Committee of the Royal Society [5] estimate that 10 per cent. should be allowed for waste. Th amount consumed would, therefore, according this estimate, be on an average 10 per cent. belo the amounts stated in the following tables.

As the food requirements of men, women, an children of different ages vary it is obviously necessar in dietary surveys to have a standard of compariso The standard taken is the food requirements of a average man. The man value standard used in th earlier studies in Great Britain was that of Atwater Atwater, however, under-estimated the food requir ments of both women and children. In Lusk's standard, which was used in later investigations, th requirements of women and children were increase In the present investigation the Cathcart standar given below is used. The main difference betwee

Cathcart's Standard of Food Requirements.

Man	1·00	Child 8–9	0·
Woman	0·83	,, 6–7	0·
Boy 14	1·00	,, 3–5	0·
Girl 14	0·83	,, 2	0·
Child 12–13	0·90	,, 1	0·
,, 10–11	0·80	,, 0	0·

the Cathcart and Lusk standards is that the form assesses the requirements of children under 2 years a lower level and of children of 8 and 9 at a high level than Lusk.

* Part of the expenses of this Survey was defrayed by a grant made to the Department of Health for Scotland by the Empire Marketing Board. The Nutrition Committee of the Medical Research Council were kept informed of the progress of both this and the previous investigation on the effect of milk on school-children, and acknowledgment is made for the helpful advice and criticisms obtained from the Committee, who are, however, not in any way responsible for the accuracy of the data or views expressed.

In considering the man value of each family in this tudy, no account was taken of the nature of the ccupations of the adults. All adult males are given value of 1·00, and all adult females one of 0·83.

In most of the surveys made in this country atten- ion has been confined to the energy-yielding onstituents of the diets—viz., the proteins, fats, and arbohydrates. It will be convenient, therefore, in omparing the results obtained in this survey with revious work to deal with these first, and then later ith the calcium, phosphorus, and iron contents hich were also calculated in the present survey.

Results.

A. ENERGY-YIELDING CONSTITUENTS.

Table I. gives the mean value with standard devia- ion and coefficient of variation for the 607 households.

TABLE I.—*Per Man Value per Day.*

—	Man value.	Calories.	Protein.	Carbo-hydrates.	Fat.
lean ..	4·86	3608·9	107·78 g.	574·43 g.	86·11 g.
tandard D.	1·68	755·4	24·68 g.	128·62 g.	24·71 g.
o-efficient of variation	34·6	20·93	22·90	22·39	28·69

The consumption in the individual households aried widely from the average figures quoted above, s is shown by the size of the standard deviation and oefficient of variation as well as by Table II., which ives the number of households in which the caloric ntake and the consumption of protein, carbohydrate, nd fat fall within the ranges indicated. The orizontal lines indicate the limits for the generally ccepted standard for an adequate diet.

TABLE II.

Calories.		Protein.		Carbohydrates.		Fat.	
Amount	No. of cases.	Amount (g.)	No. of cases.	Amount (g.)	No. of cases.	Amount (g.)	No. of cases.
500–1750	1	40– 50	1	200–250	1		
750–2000	1	50– 60	7	250–300	—		
000–2250	11	60– 70	18	300–350	11	20– 30	1

Calories.—The average consumption in calories ound in representative previous studies in Britain are s follows :—

	Calories.
Noel Paton,[8] Edinburgh, 1900, for 19 families.. ..	3233
Medical Research Council Investigation,[9] 1924, 140 miners' families, Scotland and England..	3005
Hill, Essex,[10] 1925, 90 families	2872
Medical Research Council,[11] 1926, 79 families	2686

In the United States, Sherman and Gillett,[12] n a study of 92 families, found 11 below 2000 calories, nd 22 above 3500. McKay, Ohio,[13] in 47 families found an average of 3587 calories. In a study in Tennessee[14] with 64 families, the average for the town was 3650 and for the country 3731. In Georgia,[15] in a study of 14 families, the average was 4243. In other countries Mason[16] estimates the pre-war food consumption in Germany as 4780, and Komu and Sokamoto[17] give records of two Japanese labourers with diets averaging 3768.

In all the previous studies which included a consider- able number of families there was found, as in the present investigation, to be a wide variation in the caloric consumption. For example, in Noel Paton's study of 19 families the range was from 1834–4796. In McKay's of 47 families the range was from 2081–5828. In the Medical Research Council investigations of 79 families the range was from 1396 to 3916 calories.

It is difficult to compare the results of the present survey with former ones owing to the different standards of man value used. In Noel Paton's Edinburgh studies Atwater's standard was used, and in the later ones Lusk's. The difference between the man values of the average family on the two standards has been found to be about 14 per cent. Cathcart's standard used in the present survey would be higher or lower than Lusk's according to the ages of children in the family. The other complicating factor already referred to is that the present investiga- tion merely gives the amount of food used in the house without making any allowances for wastage whereas in the other studies made in this country the amount actually consumed was determined. As already indicated the wastage not deducted in the present investigation is probably about 10 per cent. Taking account of these factors it would appear that the average found in the present investigation is slightly higher than that of previous investigations in this country, but is lower than three out of the four United States studies, and lower than Mason's estimations for pre-war Germany, or Komu and Sokamoto's records for Japanese labourers.

Calorie Requirements.—The standards for an adequate diet as set by various authorities vary from 3000 to 3500. Table II. shows that out of the 607 families, 127 fall below 3000, and 312 are above 3500. On the arbitrary assumption that 2500 is the lower limit for a sufficient diet, 29 houses out of the 607 were receiving too little food. On the other hand, in 171 houses the amount of edible food entering the home was over 4000 calories per man—an amount which indicates either an unnecessarily high consump- tion or excessive waste.

Table III. shows the proportion of the total number of calories supplied by protein, fat, and carbohydrates respectively in the seven towns.

TABLE III.—*Per Man per Day.*

No. of families	Town.	Protein.		Carbo-hydrates.		Fat.	
		g.	%	g.	%	g.	%
106	Edinburgh	100·3	12·4	516·3	63·4	84·4	23·5
57	Glasgow	108·9	12·1	575·2	63·9	95·5	24·0
37	Dundee	97·9	11·9	538·0	65·4	82·2	22·7
143	Aberdeen	107·9	12·5	561·0	65·1	84·8	22·3
103	Peterhead	126·1	12·5	685·7	68·2	85·2	19·2
31	Paisley	107·2	12·9	577·9	65·2	88·4	22·6
130	Greenock	101·7	11·9	557·7	64·8	86·9	23·0

There is a remarkable degree of uniformity between the different towns. In Peterhead the percentage of carbohydrates is higher and that of fat lower than in any of the other towns. This is due to the fact that the consumption of syrup and treacle appears to be greater, and that of butter and margarine less in this

town than in the others. The average percentage for the total households of all the towns as calculated from Table I. is: protein 12·3, carbohydrates 65·5, fat 22·2. This approximates very closely to the standard proposed by the U.S. Division of Food and Nutrition as the standard proportion for army diets: protein 12·5, carbohydrates 62·5, fat 25·0.

Protein.—The percentage of protein found in the present investigation is higher than that of most of the previous British studies. In the four already quoted, Edinburgh [8] gave 13·6, Miners [9] 10·0, Essex Rural [10] 10·7, and Scottish Urban and Rural [11] 11·3.

In the present study 41·7 per cent. fall below 100 g., but only 8, or 1·3 per cent., out of the 607 families receive less than 60 g.

Fat.—The fat percentage (22·2) of the present study is lower than that of any of the four British studies: Edinburgh 25·3, Miners 29·9, Essex Rural 22·9, Scottish Urban and Rural 26·4. The Inter-Allied Scientific Food Commission regarded 75 g. of fat daily (20–25 per cent. of the total energy value of the diet) as necessary, Voit [18] and Rubner [19] 55–60 g. In the present study only 6 families have a consumption of less than 40 g. daily, and only 13·3 per cent. fall below 60 g.

The foregoing consideration of the data on the energy-yielding constituents shows that there is no general shortage of any of these in the diets of the households studied. Of 607 families in only two cases is the intake below 2000 calories. Only eight received less than 60 g. protein, and only six less than 40 g. fat per man value. There is thus no evidence of any widespread under-nutrition.

B. NON-ENERGY YIELDING CONSTITUENTS—CALCIUM, PHOSPHORUS, AND IRON.

The mean standard deviation and coefficient of variation for calcium, phosphorus, and iron are shown for the seven towns singly in Table IVA., and combined in Table IVB.

The mineral content has not been estimated in dietary studies previously undertaken in Britain, but figures are reported from studies in other countries.

Calcium.—Sherman, Mettler, and Sinclair,[20] in an American dietary study calculated the average calcium consumption to be 0·57 g. per day for a man 0·59 g. for a woman. Tigerstedt,[21] in Finnish diets found that the daily calcium intake ranged from 1·58 g. for children 2–3 years old up to 3·79 g. for men. Horneman,[22] in 1913, estimating food actually consumed in German households, found the calcium intake to be for a man 1·227 g., for a woman 0·615 g. and for a 6 year old child 0·427 g. Sherman and Gillett (loc. cit.) in the 92 American dietaries, showed the average calcium consumption to be 0·72 g.

In the present study the mean of the combined Scottish towns is 0·86 g. The high calcium intake appears to be due to a more liberal supply of milk and treacle, both of which are rich in this element.

From all the evidence available Sherman,[3] in 1927 calculated the minimum maintenance requirement in calcium to be 0·45 g. daily, and considers 0·68 g. necessary to allow a margin for safety. From Table V., which gives the range of intake, it will be seen that 47 families, or 7·7 per cent., fall below 0·45, and 149 or 24·5 per cent., fall below 0·60 g. which is slightly below Sherman's safety limit and roughly about 20 per cent. fall between 0·60 and 0·75 g.

Phosphorus.—The average phosphorus consumption in Sherman, Mettler, and Sinclair's (loc. cit.) study was 1·40 g. per man, and 1·21 g. per woman. Tigerstedt's (loc. cit.) Finnish diets showed an intake ranging from 1·18 g. for 2–3 years old children up to 4·33 g. for men. Sherman and Gillett's (loc. cit. 1917 study gave an average intake of 1·52 g. The present study shows a mean of 1·70 g. in the combined towns, which individually range from 1·44 g. (Dundee) up to 2·14 g. (Peterhead, which has the highest mean calorie and protein intake). Sherman indicates the minimum requirement in phosphorus to be 0·88 g. daily which with the 50 per cent. safety margin becomes 1·32 g. In this Scottish study 14, or 2·3 per cent., fall below 0·90 g. and 140, or 23 per cent., below 1·35 g.

Iron.—There is very little definite information in the literature on the requirements of men for iron or on the amounts actually consumed. Horneman (loc. cit.) found consumption to be 54·67 mg. for a man, 31·82 mg. for a woman, 18·76 mg. for a 6 year old child. Sherman and Gillett (loc. cit.) found the intake to range from an average of 12·1 mg. in the cheaper diets to one of 20·6 mg. in the more expensive, giving an average for the 92 households of 16·3 mg. In the present study the average of the combined Scottish towns is 14·3 mg., ranging from 11·3 mg. in Dundee to 20·2 mg. in Peterhead.

Sherman from his own and other experimental data on iron elimination, concludes that 15 mg. daily is required. If we accept this figure as the standard, 61·6 per cent. of the 607 families must be regarded as receiving an insufficient amount of iron in the diet.

Table V. gives the number of households in which the consumption of calcium, phosphorus, and iron falls within the ranges indicated.

The horizontal lines are placed to give an indication of the optimum intake in so far as can be determined from the limited information available. It is seen that there is a large proportion of the households in which there is a definite shortage of one or more of these three nutrients. In the present state of our knowledge, however, it would be unsafe to draw any definite conclusions from these figures. It is to be regretted that we have not more information with regard both to the requirements and the consumption of these nutrients. This is obviously an aspect of

ıman nutrition on which more work is urgently eeded.

Diets in Relation to Growth.

The standards referred to above have been fixed the requirements of adults whose needs are only ose of maintenance—i.e., the amounts of the fferent dietary constituents for replacement of the ss in "tear and wear" of the tissues. In addition this maintenance requirement, children need aterial for the construction of new tissues in growth. nfortunately, less work has been done on the growth quirement of children than upon the maintenance quirements of adults, though from the point of view health the former is probably the more important. 'e are indebted for whatever information we have iefly to Sherman and his co-workers.

Sherman and Hawley, as the result of balance periments with children, estimated that children om 3 to 13 years of age need 1 g. of calcium and om 1·16 to 1·46 g. of phosphorus per day. Sherman so considers that the need of the child for iron is eater proportionately than that of the adult. ı accordance with these findings, Hawley [23] has awn up the following scale of man values for otein and mineral requirements.

Hawley's Scale for Protein and Mineral Requirements.

an	18 to 60	1·0	Girl 13 to 14	1·3
oman	,, ...	0·8	,, 10 to 12	1·2
outh	15 to 17	1·5	Child 6 to 9	1·0
rl	,, ...	1·2	,, under 6	0·8
oy	10 to 14	1·3		

To ascertain the average consumption on this growth quirement scale the man value for Dundee was calculated on the Hawley standard. On this andard the mean man value was 7·19 as compared ith 5·46 on Cathcart's standard. The average otein and mineral consumption in Dundee on the vo scales is given below.

Comparing Cathcart's scale on which the man value calculated on an energy requirement basis with that Hawley on which it is calculated on the require-ents of growth, it is seen that on the latter basis ıe diet provides roughly nearly 25 per cent. less of protein, calcium, phosphorus, and iron per man unit.

—	Cathcart's scale, based on energy requirements.	Hawley's scale, based on requirements for growth.
Protein (g.)	97·90	74·77
Calcium (g.)	0·70	0·53
Phosphorus (g.) ..	1·44	1·101
Iron (g.)	0·0113	0·0087

We have seen that calculating the intake according to Cathcart's scale the number of families which fall below the standards for these substances was 41·7, 24·5, 23·0, and 61·6 per cent. respectively. On the Hawley scale these numbers would, of course, be greatly increased. This is brought out in Table VI., in which the diets are calculated on the basis of this scale.

TABLE VI.—*Range on Hawley Scale (Dundee).*

Protein.		Calcium.		Phosphorus.		Iron.	
Amount (g.).	Cases.	Amount (g.).	Cases.	Amount (g.).	Cases.	Amount (g.).	Cases.
						0·0030–0·0045	1
						0·0045–0·0060	1
40– 50	1					0·0060–0·0075	8
50– 60	2			0·600–0·750	1	0·0075–0·0090	14
60– 70	13			0·750–0·900	4	0·0090–0·0105	9
70– 80	8	0·150–0·300	1	0·900–1·050	10	0·0105–0·0120	2
80– 90	8	0·300–0·450	7	1·050–1·200	11	0·0120–0·0135	1
90–100	4	0·450–0·600	20	1·200–1·350	9	0·0135–0·0150	1
100–110	1	0·600–0·750	7	1·350–1·500		0·0150–0·0165	
110–120		0·750–0·900	1	1·500–1·650	1	0·0165–0·0180	
		0·900–1·050	1	1·650–1·800	1		
	37		37		37		37

From the table it is seen that out of 37 families only one had over 100 g. of protein; nine over 0·6 g. of calcium; two over 1·35 g. of phosphorus, and none over 0·015 g. of iron, the standard requirements according to Sherman. On the whole the average intake of these substances is lower in Dundee than the average for the whole seven towns. This city has the lowest average for phosphorus, lowest average for iron, and third lowest for calcium. The percentage of families receiving less than the standard requirements would not be so high in the other towns. Even allowing for this however, a superficial examination of Table V. in the light of Table VI. shows that probably the majority of families in all the towns are on diets with less than the optimum amounts of protein and these three minerals.

The only other dietary survey carried out under comparable conditions and calculated to this scale is that of McKay (loc. cit.) for 47 families in Ohio. The average consumption as found by McKay is compared with the average consumption in the present survey in the following figures:—

—	Ohio.	Scottish Towns.
	Average.	
Calories	3587	3609
Protein	92·9 g.	74·77 g.
Calcium	1·087 g.	0·532 g.
Phosphorus ..	1·594 g.	1·101 g.
Iron	0·0163 g.	0·0087 g.

The difference between the composition of the diet in Ohio and in these Scottish diets is striking. The former is wholly adequate for growth with regard to

the constituents named. Compared with the average Ohio diet the Scottish diet, while rich enough in energy-yielding constituents, contained only from one-half to two-thirds as much of these nutrients required as constructive material in growth.

Discussion of Results.

In the milk tests on school-children, in connexion with which the present survey was made, more than one-third of the children came from the households studied in the present survey, and these households were chosen as representative of the homes of all the children. It is of interest, therefore, to consider the results of the milk tests in the light of the results of the survey. In the tests it was found that the giving of extra milk was followed by increased rate of growth, as determined by both increased height and increased weight. The increase was from 20–40 per cent. in each of three groups of different ages in the whole of the seven cities and towns. Separated and whole milk were found to be of practically the same value for growth for school-children. On the other hand, the addition of carbohydrate and fat-rich biscuits had no effect on growth. The finding that the additional fat and carbohydrate given in the biscuits had no definite effect, combined with the finding that the whole milk, including the fat, had little or no greater effect than the separated milk without the fat, could only be explained on the grounds that the caloric intake of the children was on the whole sufficient for their needs. This is in agreement with the results obtained in the dietary survey.

Factors common to both separated milk and whole milk are proteins and minerals. The survey shows that a large proportion of the diets had less than the amounts of protein, calcium, phosphorus, and iron necessary to maintain optimum growth. It seems probable, therefore, that at least some of the effects of the separated milk can be attributed to the protein and minerals.

The results of the survey seem to indicate that there is a shortage of calcium, phosphorus, and iron in many of the urban diets. Our information with regard to the requirements of these is, however, very inadequate. Further, there are very little data with which those of the present survey can be compared. It would be unsafe, therefore, to draw any far-reaching conclusion from the results of the present survey. They are, however, of sufficient interest to warrant the suggestion that more information is urgently needed both on the requirements for those nutrients and on the intake.

No attempt was made to assess the vitamin value of the diets. The omission is due, not to lack of appreciation of their importance, but to the fact that in the present state of our knowledge neither the vitamin content of the foodstuffs nor the vitamin requirements of individuals at different ages can be expressed in units suitable for statistical treatment. It is more than probable, however, that there may be a deficiency of some of the vitamins especially, in view of the results obtained with milk, of those concerned with calcium assimilation and with growth.

If the tentative conclusions of the survey can be regarded as even approximately accurate, it is evident that the dietaries of these urban households would be greatly improved by an increased consumption of milk and green vegetables. Milk is the best and cheapest source of protein and calcium. It is also rich in phosphorus. Green vegetables are rich in both calcium and iron. In addition to these nutrients milk and vegetables would also enrich the diet in those vitamins liable to be lacking in a carbohydrate-rich diet.

Summary.

The main points brought out by the statistic analysis of the diet are as follows:

(1) In 607 families in seven Scottish towns th average diet, taken as the amount of edible materi entering the house and calculated on Cathcart standard of man values, was found to have a calor value of 3609, with 107·8 g. protein, 574·4 g. carb hydrate, and 86·1 g. fat per man value.

(2) The mineral content of the diets was als estimated using the same man value scale. Th showed an average amount per man of 0·86 g. calciun 1·70 g. phosphorus, and 0·0143 g. iron.

(3) Of the 607 families the following percentag were found to be below the generally accepte standards of requirement for adults for the foo constituents dealt with; protein, 41·7 per cent. fat, 13·3 per cent.; calcium, 24·5 per cent.; phosphoru 23·0 per cent.; and iron, 61·6 per cent.

(4) The diets for one town (Dundee) were r calculated on the Hawley higher man value scal which takes into account the requirements in protei and minerals for growth in children. The averag amount per man value on this scale was found to be protein, 74·77 g.; calcium, 0·53 g.; phosphorus, 1·101 g and iron, 0·0087 g.

(5) In this town the standards of intake necessar for optimum growth were reached in the case of th 37 families studied in only one case for protein, nin cases for calcium, two cases for phosphorus, and nor for iron.

(6) The results of the survey indicate that th diets are, on the whole, adequate as regards the energy value. Comparatively few fall below th minimum necessary for health. Only 29 out of th 607 families are below 2500 calories, which is sufficien for a man not doing manual labour. Only tw families fall below 2000 calories. There is thus n indication of any extensive gross under-nutrition.

(7) When the diets are considered from the point view of their adequacy to support optimum growt the results are less satisfactory. The diets are po in protein and poorer still in the minerals estimate According to Sherman's standard of requiremen the great majority of the diets are incapable supporting the optimum rate of growth.

TUBERCULOSIS SCHOLARSHIP TOUR.

(FROM OUR OWN CORRESPONDENT.)

Two years ago a party of Canadian medical men nd women visited this country to make a study of berculosis work, and a return visit was paid last onth by a group of 50 British medical men and omen. The itinerary was planned by Dr. W. E. odehouse, secretary of the Canadian Tuberculosis ssociation, and both tours were made possible by e offer of scholarships from the Sun Life Assurance mpany of Canada.

QUEBEC AND MONTREAL.

The s.s. *Duchess of Bedford* was due to arrive at Quebec rly on the morning of Friday, August 15th, but as delayed by fog until the evening, and the proamme for the day had to be cut out, save for a ry late dinner at the Château Frontenac, given by e Provincial Government. Montreal was reached xt day, and on Sunday the real business of the ur began with an inspection of the Sacred Heart spital, Cartierville. This is a magnificent building anned, organised, and owned by a Roman Catholic terhood, but with an independent medical staff tached to the Montreal General Hospital. The ernoon programme included a visit to the country tate of Mr. T. B. Macaulay (President of the Sun fe Assurance Company) and an inspection of his nderful herd of Frisian cattle which have had a gative tuberculin test for seven years. The cterial count of the milk is now almost nil.

OTTAWA.

At Ottawa next day an inspection of Parliament uildings was followed by a visit to the Research aboratories of the Health of Animals Branch, deral Department of Agriculture. Here four short tures were given. Dr. A. E. Cameron outlined e methods adopted for the control and eradication bovine tuberculosis in Canada; Drs. Hoefflin d Stanley gave a study of the blood picture in vine tuberculosis; Drs. McIntosh, Watson, and nst gave a comparative study of vaccination with ing tubercle bacilli, with especial reference to C G; and Dr. C. A. Mitchell a comparative study the biology and pathogenicity of tubercle bacilli avian, bovine, and human origin. The next visit s to the Royal Ottawa Sanatorium, a well-equipped d up-to-date institution, the cost of which is borne the city, aided by a grant from the province of tario. A brief visit to the Civic Hospital, which s a few beds for tuberculous patients, a tour of the y, and dinner at the Château Laurier as guests of e City of Ottawa, completed the second day.

TORONTO.

Toronto was reached on Tuesday morning when a thological demonstration was staged at the Hospital Sick Children by Dr. H. C. Parsons, physician in ief, and Dr. Erb, pathologist to the hospital. Dr. Erb showed a number of post-mortem specimens from children dying from tuberculous meningitis and miliary tuberculosis. The specimens showed a small primary focus in the lung with corresponding lesions in glands draining that portion of the lung. A second group of cases illustrated the point that as the disease progresses and the mediastinal glands enlarge, the mediastinum takes on the appearance of a large tumour. The third group illustrated certain types of accident that may occur in persons with mediastinal tuberculosis—e.g., caseous glands breaking down into a bronchus, with resulting fatal aspiration, pneumonia, thrombus in the right pulmonary artery, &c. Dr. Parsons said that the Chest Clinic was started with a view to ascertaining how much tuberculosis was communicated to children by adults. They also wished to find out the way in which early tuberculosis started. They had become convinced that the main feature was mediastinal in the early stages rather than pulmonary. Practically all the tuberculosis in Toronto was of human type. The material in the hospital was definitely selected, the chest clinic automatically getting all the contacts immediately, also all children from school clinics suspected of tuberculosis. Children with positive tuberculin tests and no clinical or physical signs are believed to be invariably suffering from tracheobronchial tuberculosis. Prof. Schick in a recent visit to the hospital concurred in this view.

A visit to the diagnostic clinic at the Gage Institute, of which Dr. W. J. Dobbie is the physician in chief, was the next item. At this clinic 65,550 persons have been examined, the average number at present being 500 per month. Nearly all these patients are sent by physicians in Toronto and from within a radius of 50 miles of the city. No treatment whatever is given at the clinic. Dr. Dobbie is also physician in chief of the Toronto Hospital for Consumption which has a daily average number of 350 patients in residence. This was the first hospital for advanced cases of tuberculosis established anywhere in the world. Another institute visited was the Christie Street Hospital, containing about 350 beds, which is maintained by the Federal Department of Pensions and National Health for ex-Service men. A visit to the Connaught Laboratories and School of Hygiene in connexion with the University of Toronto was arranged for the remainder of the afternoon. In these laboratories research is carried out in various fields of preventive medicine, and biological products—diphtheria and tetanus antitoxins, liver extract, insulin, &c.—are prepared. The day finished with a dinner given by the Provincial Government of Ontario to the members of the tuberculosis party.

On Wednesday a demonstration was given by Dr. G. C. Brink, of the Travelling Clinic, for the diagnosis of diseases of the lungs, of which the Government bear the whole cost. The staff of the clinic consists of from one to three physicians and a nurse. The equipment includes a portable X ray unit, and X ray films are taken of every case. Tuberculin tests are done on all children under 16 years of age.

A short inspection of Hart House, the well-equipped non-residential quarters of the University Students' Union, was followed by a visit to the Children's Preventorium. This was opened in 1910 with 100 beds for tuberculin-reacting contacts of sputum positive cases in the city. No definite cases of pulmonary tuberculosis and no surgical cases are admitted. The duration of stay is up to nine months, but may be indefinitely prolonged where the home conditions are bad.

BALA.

A night journey to Bala enabled the party to board the steamship *Cherokee* in time for breakfast. Two or three hours were spent on Lake Muskoka, winding in and out of the hundreds of thickly wooded islands, till Calydor Sanatorium was reached. This very beautiful hospital, of which Dr. Parfitt is physician in chief, was established 14 years ago for private patients. Two types of patient are received here: those who come for diagnosis and only make a short stay, and those who are very ill and stay on for indefinite periods to get well. When the tour of the sanatorium was completed the members of the Beaumaris Yacht Club kindly took the whole party for a delightful trip on the lake in a number of motor boats, and afterwards entertained their guests at lunch. A move was then made to the Muskoka Cottage Sanatorium for private patients, the first sanatorium in Canada, opened in 1896. Both this institution and the Muskoka Hospital for Consumptives are under the care of Dr. W. B. Kendall, and both were intended at first only for incipient or early cases of tuberculosis. At present, however, moderately advanced and advanced cases form an overwhelming majority of the patients. Both these institutions appear to be ideal for their purpose in regard to climate, situation, amenities, design, equipment, and medical care available.

After dinner at the Muskoka Hospital the steamer was boarded for the return trip across Muskoka Lake, the party entraining late that night at Bala for the long railway journey to Ninette, Manitoba, where the week-end is to be spent as the guests of the Manitoba Sanatorium Board. On Monday afternoon the party will entrain for Winnipeg, where the British Medical Association meeting is to be held. At the end of the meeting the party will leave for Chicago and other cities in the United States. The tour ends officially on Sept. 5th, but many individual members are planning to extend it.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

MEDICAL ADVERTISING BY GROUPS.

THE success of public health advertising by county medical societies in New York, Ohio, and elsewhere is resulting in a new crop of experimental advertising campaigns. The movement has reached the State of Washington on the west coast, and 80 members of the Pierce County Medical Society have subscribed $4500 for use in their locality. An advertising agency in Seattle is acting as consultant, but all published articles are passed upon by a committee of the society. The advertising "messages" appear in the first place in the three county newspapers, then each is reprinted in leaflet form for distribution by the doctors to their patients. Finally they are bound together with a roster of the county medical society, and presented to the public libraries and schools.

"The articles," it is stated, "will make known essential facts in the progress of medical science, the real work and aims of the organised medical profession, and its every-day relation to all classes of people. The qualifications demanded of the competent physician to-day, and the standards by which he is identified may be indicated. It is believed that this work will result in a broader knowledge of public health and assist materially in the prevention of disease; and it is for these reasons that the educatio campaign has been undertaken."

IMMUNOLOGY OF SCARLET FEVER.

The use of scarlet fever streptococcal toxin and corresponding antitoxin for the prevention and tre ment respectively of scarlet fever was discussed the annual conference of State and territorial hea officers with the U.S. Public Health Service. T conference was reminded by Dr. M. V. Veldee t four years ago they had come to the follow conclusions: (1) The intradermal reaction to scar fever streptococcus toxin is a fairly depend measure of the susceptibility of the individual test (2) The majority of the individuals giving a posit reaction can be effectively immunised by the pro use of scarlet fever streptococcus toxin. (3) T use of scarlet fever streptococcus antitoxin, either passive immunisation or for the treatment of individual ill with scarlet fever, is not yet founded sufficient clinical data to permit a mature opinion to the efficacy of this form of treatment. The la amount of research since that time had given lit reason, he believed, to alter these conclusio Probably 90 to 100 per cent. of persons giving Dick-positive reaction can be converted to Di negative reactors by the injection of scarlet fe streptococcus toxin. The effect that such prophyla may have on the incidence of scarlet fever in a la community cannot at present be stated, tho encouraging statistics are reported in the *Journal Infectious Diseases* by Toyoda [1] and his co-work in Manchuria. There are also certain practi difficulties of administration which retard the adopt of this method of prophylaxis. Dr. Veldee refer especially to the uncertainty existing as to the num of injections to be given, and the disadvantages giving many injections of a solution relatively high protein content. He felt that we need a prod which will be satisfactory with fewer doses, and give rise to less reaction.

TOXIN-ANTITOXIN AND TOXOID.

At the same conference Dr. W. T. Harrison repor a study made at the National Institute of Hea (formerly the Hygienic Laboratory) on the comparat merits of toxin-antitoxin and toxoid. Tests w made on comparable groups of children under stric controlled conditions. Schick tests were given bef and at a stated interval after immunisation. T test in children who received toxin-antitoxin v controlled with heated toxin, that in the child who received toxoid by toxoid diluted in 1 in physiological saline solution. Various commer samples were used, and one sample of toxin-antito prepared in the laboratory of the institute. Diphthe toxoid was found to be "practically an ideal agen both on account of the complete absence of local general reactions, and the very high percentage successful immunisations following two injectio The injections, of 1·0 c.cm. each, were given at interval of one month. In 475 children immuni as measured by the Schick test, was conferred 95 per cent. of cases. In the group receiving tox antitoxin, only 64 per cent. were successfu immunised.

APPENDICITIS.

In its July bulletin, the Metropolitan Life Insura Company draws attention to the large and increas number of deaths from appendicitis. More t 18,000 deaths were recorded from this cause in United States in 1928. The increase is believed to

real one, and not due in any large degree to greater ecision in the filling out of death certificates. general health examinations in recent years, tween 2 and 3 per cent. of males have shown nderness in the appendix region. It is suggested at critical research is needed to uncover the causes ding up to inflammation of the appendix.

"JAKE" PARALYSIS.

A preliminary communication from the National alth Institute[2] announces that the mystery of ake" paralysis is solved. The poison is a phosoric acid ester of one of the cresols. An adulterated ger made up from the U.S. Pharmacopœia fluid tract but containing 2·7 per cent. of tricresyl osphate (technical) gives all the effects in rabbits l monkeys that samples of suspected Jamaica ger had given. The rabbits were poisoned, the nkeys escaped. The isolation of this phenol npound was greatly assisted by the bureau of hibition who were able to supply large quantities seized Jamaica ginger, some of which was known to ong to batches which had caused poisoning. It nteresting that the ester is apparently not broken vn by dogs or monkeys, and large doses can be en by them without injury. Rabbits suffer from nol poisoning. Calves also suffer with a type paralysis more closely simulating that found in man.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

INCREASE OF HEART DISEASE.

Prof. Leschke of the Charité Hospital, Berlin, lately been commenting on the great increase heart diseases. Whereas the death-rate from this se was 161 per 100,000 in 1911 it had increased 189 in 1927. This is the more remarkable because general mortality decreased considerably during same period. Every form of heart disease has reased with the exception of pericarditis, while ditions due to rheumatic, bacterial, or syphilitic ction and to overstrain of the heart and vessels e become a great deal more common. During the , and immediately after it when influenza was ecially severe, endocarditis and myocarditis as a uel to streptococcal infection were responsible a large number of deaths. In Leschke's opinion increase of syphilitic affections of the heart and vessels is not a result of salvarsan therapy, as has n suggested. Of his own cases 88 per cent. had been treated by salvarsan at all. On the other d the beneficial action of salvarsan will not be ious for some years, since the interval between ction and the development of syphilitic aortitis usually between 6 and 40 years. Economic iculties, the struggle for existence, and the uence of tobacco, spirits and strong coffee, are ong the factors he holds responsible for heart ase and he advocates individual prophylaxis inst circulatory fatigue. An advantageous uence is the tendency of the younger generation bstain from spirits and tobacco and to indulge in ies and sound athletic exercise.

The increase of thrombosis and embolism is sometes attributed to the increase of intravenous injections, but the majority of sufferers have not received any such injection.

POLIOMYELITIS IN GERMANY.

Infantile paralysis has become prevalent in several parts of southern Germany, especially in Baden. The source of infection is obviously Alsace, where it is said to have been common for some time. From Baden it has spread over northern Germany and up to August 16th, 510 cases had been notified in the country as a whole. Notification is compulsory and in some of the German states the health authorities must be informed if the diagnosis is so much as suspected. According to a Prussian law patients suffering from, or suspected of suffering from, poliomyelitis must be isolated; the rooms must be disinfected and child contacts are not admitted to school. In a Berlin grammar school and in certain municipal schools there have been some fatal cases and some of the classrooms have been provisionally closed. Parents whose children are attending these schools are somewhat nervous, and this has led the Municipal Health Office to make an official statement that the spread of the disease is comparatively slow and that the danger of catching it is much smaller than in scarlatina, diphtheria or measles.

A LARGE INFANT.

Dr. Kötter, writing to the *Centralblatt für Gynäkologie* describes the birth of a child 6284 g. (about 13¾ lb.) in weight and 61 cm. long. The infant was born spontaneously and labour was fairly quick, the only difficulty being that the passage of the shoulders was delayed in the pelvis. Living infants of 6000 to 7000 g. are very rare; indeed only five cases are described in medical literature. The causes of the gigantism are not fully understood; troubles of internal secretion, superabundant nourishment, diabetes, racial or constitutional pecularities of the parents, and an abnormally quick growth of the fœtus have all been put forward as responsible.

KALLIKREIN.

Dr. Frey has reported to the Berlin Medical Society on a hormone obtained from the pancreas which exerts, he says, a powerful influence over the circulation by dilating the blood vessels. The new hormone is present in urine and disappears therefrom if the pancreas is removed. It is produced commercially under the name of Kallikrein by the Farbwerke factory and this preparation is administered by intramuscular injection. It is said to lower high blood pressure considerably, but leaves normal pressure unaffected. Low blood pressure may even slowly increase, which suggests that the hormone has a regulating action. In the treatment of angina pectoris the attacks are said to have ceased rapidly. Frey drew special attention to the excellent effects noted in intermittent claudication; in cases of early gangrene and necrosis amputation could be avoided by giving kallikrein. In the discussion of his paper good results secured in several hospitals were reported by other speakers.

A MEDICO-LEGAL QUESTION.

A remarkable judgment was recently given by the High Court in Leipzig. A patient telephoned to a medical man (Dr. A.) asking him to see her. The doctor's wife replied that he would come at once, but in her husband's absence she sent a locum tenent to the patient. The treatment given by the latter proved unsatisfactory and the patient eventually brought

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN WINNIPEG.

(*Continued from p. 542.*)

SECTIONS OF SURGERY AND TUBERCULOSIS.

AT a joint meeting of the Sections of Surgery and Tuberculosis Prof. E. W. ARCHIBALD (Montreal) opened a discussion with a paper on the scope of

Thoracic Surgery.

This was, he said, the latest of the specialties, and hitherto the best work in it had been done by general surgeons who had made it their hobby. Eventually, however, he believed that surgeons would devote their time exclusively to this one branch of surgery. Team-work was a necessity, and was now almost the rule wherever real progress was made. In his own thoracic clinic, surgeons, physicians, and pathologists worked together in close collaboration and free discussion always preceded surgical measures.

Discussing indications for treatment, Prof. Archibald said that operation should not be attempted in a tuberculous patient unless there was evidence of resistance, as shown by fibrosis or scar tissue. He divided patients into three classes: (1) "good chronics" or favourable cases; (2) conditionally favourable cases; and (3) unconditionally unfavourable cases—i.e., those with cavities or mixed infections. In his own series the operative mortality in class 1 was 3·5 per cent.; in class 2 3·6 per cent.; in class 3 28·5 per cent. The mortality thus varied directly with the class of case, so that very careful selection was required. With regard to lung abscess, two things were worth noting: first, that sometimes in the past too much had been done for such cases, since 40 per cent. of them would cure themselves if left alone; secondly, that sometimes in the past too little had been done for chronic cases. Cases of bronchiectasis could be divided into two groups: (1) the simple or uncomplicated, for which artificial pneumothorax or phrenicotomy was suitable; and (2) the complicated with chronic suppuration accompanied by parenchymatous infiltration, for which either a one-stage or a multiple stage lobectomy was indicated. The results of a one-stage lobectomy were so encouraging that this operation would probably be the rule in cases of unilobar disease.

(*Continued from previous page.*)

an action for damages against the medical man and the locum tenent. The High Court found for the plaintiff and held that not only the locum tenent but also Dr. A. was responsible; the patient had desired that Dr. A. should attend her, and from his wife's answer had concluded that this would be so. Although Dr. A. was prevented from coming the patient had made the agreement for medical attendance with him and therefore he and his locum tenent were liable to pay damages. This was the more apparent as the bill for medical attendance was sent to the patient by Dr. A.

On another judgment the High Court has decided that if the wife of a medical man, as may happen in country practice, gives first-aid to a patient in her husband's absence, she alone is responsible for any mistake she makes. But if the medical man sends a bill to the patient he becomes responsible, for his wife is then to be regarded as his unqualified assistant.

THE MEDICAL ASPECT.

Dr. R. A. YOUNG (London) thought the help th surgery could give, in those grave intrathorac conditions where medicine was impotent or limit to palliation, was not as widely recognised as should be—thoracic surgery was, indeed, daily givi results comparable in value with those of abdomir surgery and without prohibitive risks. The medic aspects of this development were difficult to defi They involved: (1) diagnosis of the condition; (assessment of the patient's suitability for operatio (3) choice of surgeon; and (4) discussion of t operative measures proposed and their adaptati to the needs of the patient. The diagnosis of int thoracic disease, especially of morbid conditions the bases of the lungs or of the mediastinum, mig be very difficult, but fortunately there was usual time for the full investigation which was necessar The advance in radiological technique had contribut largely to the advance in diagnosis and surgi treatment of intrathoracic disease, and comple radioscopic and radiographic investigations were n essential in almost every case. As a physici Dr. Young deprecated exploratory puncture random where intrapulmonary suppuration w suspected. It might be a cause of disaster if t pleura in the region of the puncture was not adhere It was a still more difficult matter to assess t patient's suitability for operation, depending as did on so many imponderable factors. Urologi had set physicians an excellent example in the hi standard of their methods of investigating re function before operation, and the speaker felt th there was scope for research in the matter of asse ment of respiratory efficiency. A very low vi capacity might be a bar to operation. At present was necessary to rely chiefly on a careful clini review. Dr. Young felt strongly that the m difficult operations in that field of surgery should o be entrusted to those with special experien Fortunately there were now teaching centres in alm all English-speaking countries where thoracic surg of the best type could be studied and where experie could be gained. Preparation for operation sho include prolonged preliminary measures for gett the patient into the best possible condition, and provision of skilled after-care and nursing.

MALIGNANT DISEASE OF THE LUNG.

Mr. A. TUDOR EDWARDS (London) said that whet or not there had been a true increase in the incide of malignant disease in the lung during the last f years, the incidence of cases diagnosed was certai much higher than it was even five or six years a Primary malignant neoplasms in the chest w extremely insidious in their onset, and by the ti the patient sought advice the mediastinal glands l usually become involved and all hopes of succes surgical removal of the growth had gone. In lung, carcinoma apparently arose primarily in t situations—the bronchi and the parenchyma. P monary endothelioma of the lung had been describ the growth being localised to a greater or less deg and consisting of masses of cells of endothelioid ty Sarcomata were much rarer than used to be thoug and many cases formerly described as sarcoma wo now be classified as carcinoma.

Symptoms and signs.—Although the onset generally gradual and insidious, many cases star with a pyrexial attack commonly labelled influe Sometimes the history might merely be one increasing lassitude without localising symptoms, symptom being later accompanied by dyspnœa

n-productive cough. Hæmoptysis occasionally peared early. Irregular pyrexia might also be an rly symptom, but the temperature was rarely high til the later stages of the disease. Pain was never vere until the pleura or mediastinum was involved. her possible symptoms included dysphagia from essure upon the œsophagus of secondary deposits mediastinal glands, and hoarseness from pressure on or involvement of the left recurrent laryngeal rve. The signs varied according to the type of sease. In the central or alveolar type physical gns might be altogether absent or might consist of alised dullness associated with weakened breath d voice sounds. Extrapulmonary signs included largement of the supraclavicular gland and ralysis of the homolateral diaphragm from phrenic rve involvement. Evidence of venous obstruction as comparatively rare in pulmonary neoplasms. æmorrhagic pleural effusions might occur, these ing usually late in their incidence.

Diagnosis.—The possibility of malignant disease ould be suggested by the fact that the signs were t typical of any of the common lung diseases, e diagnosis being further confirmed by physical, diological, and laboratory examination. Broncho-py should be undertaken wherever there was finite evidence of bronchial obstruction, as well as patients in whom hæmoptysis was a prominent mptom but in whose sputum no specific organisms uld be found on repeated search. Mr. Edwards so urged the removal of a small portion of suspected sue for histological examination. Thoracoscopy ght be of value in a limited number of cases, lowing the production of an artificial pneumo-orax or the replacement of an effusion. In cases ere the growth was superficial a definite diagnosis ght be made by this means. Exploratory thoraco-my also had a definite place among diagnostic thods. When it was carried out under modern nditions and, where possible, preceded by the duction of artificial pneumothorax, exploratory oracotomy was no more serious a procedure than dominal operation, and entailed usually less opera-ve discomfort to the patient. Intercostal incision th retraction of the adjoining ribs gave sufficient posure, rendering rib resection unnecessary except older subjects in whom the costal cartilages were ified, or when the actual removal of neoplasms or large portions of lung was contemplated.

Treatment.—Until recently no definite attempt had en made, apart from the various forms of radio-erapy, to treat malignant disease of the lung in an equate way. Owing both to the insidious onset the disease and also to the position of new growths the lung in relation to vital structures, there were vious difficulties in the way both of complete noval or of adequate irradiation of pulmonary oplasms. Cases of malignant disease arising in the all alveoli or small bronchioles, which, however, fortunately formed only a small proportion of the al cases of malignant disease of the lung, offered best chance of surgical extirpation. Bronchial cinoma rarely offered any hope of successful noval owing to the position of the growth and its ly spread into mediastinal glands.

Where radical removal of malignant growths in lung was impracticable, radium therapy should considered. Three methods were available—etherapy, external plaques, and radon seeds. Tele-erapy—the application at a distance of large doses a bomb—was painless and therefore an attractive thod, but the six patients whom he had treated this method alone had all died. The application of radium on external plaques of Columbia paste or Sorbo rubber had been used for five cases of malignant disease in the lung without, however, any improvement, save that in three cases the application had considerably relieved acute pain caused by the involvement of the chest wall by the growth. The insertion of radon seeds was another method which had definite advantages over the use of radium needles in the treatment of pulmonary growths. Even when cure was not likely, the relief given and the prolongation of life afforded by means of radium thoroughly justified the comparatively small risk entailed. Deep X ray therapy, on the other hand, was very disappointing for primary malignant lung tumours. He had never seen a patient who had benefited thereby, but the newer and more powerful types of apparatus might prove of more value.

PHRENIC NERVE AVULSION.

Dr. W. L. MANN (Winnipeg) said that collapse therapy was a natural means of curing of many lung lesions. Within a few years of the introduction of artificial pneumothorax, the first operation on the chest wall to produce collapse was done, but it was not till 1911 that paralysis of the diaphragm was suggested as an aid to collapse therapy. Dr. Mann traced the gradual improvement of the technique from the early simple section of the nerve to the realisation of the very great variation in the mode of formation of the phrenic nerve, and of the fact that a single trunk could not be assumed until well below the clavicle. Avulsion of at least 4 inches of the nerve was now the operation of choice. Discussing the signs of paralysis of the diaphragm, the speaker pointed out that the extent of the rise varied from 2 to 13 cm. and was dependent upon several factors, the most important of which was the type of lesion in the lung above. If the lesion was markedly proliferative, the diaphragmatic rise was usually great. The chief value of this paralysis was that it removed one of the forces opposing the natural healing process within the lung—i.e., the contraction of scar tissue. The paralysed diaphragm allowed collapse of scar tissue and tended to produce obliteration of cavities; it allowed a reduction in pulmonary volume varying from one-sixth to one-third; it produced a degree of pulmonary rest by removing the piston-like action of that half of the diaphragm. This affected chiefly the lower lobe, but to some extent also the whole lung. Cough and expectoration were often much easier than before. Hæmoptysis often ceased immediately after the operation; sputum might be markedly reduced in a month, cavities gradually obliterated, and general improvement in health frequently occurred. Possible dangers connected with the operation included hæmorrhage from accidental injury to the blood-vessels; air embolism following wounds of the large veins of the neck; mediastinitis, set up by drawing out the nerve through infected pleura and lung. The commoner indications for phrenic avulsion included such conditions as pulmonary or pleural cavitation, as in chronic empyema which had resisted other methods of treatment and where thoracoplasty was indicated. In bronchiectasis phrenic avulsion might be tried with or without pneumothorax. If lobectomy had been decided upon, the preliminary phrenic evulsion was of valuable assistance. The commonest indication for the operation was in the treatment of pulmonary tuberculosis, either in acute progressive cases where pneumothorax was not possible and thoracoplasty inadvisable, or as a supplementary measure in cases of incomplete pneumothorax; or,

again, in many chronic cases with cavitation and positive sputum a phrenic avulsion might allow cavities to close and symptoms to disappear. In cases of pulmonary hæmorrhage when pneumothorax was impracticable, diaphragmatic paralysis might be of great value. Avulsion should also be done as a preliminary to every thoracoplasty. While sufficient time had not yet elapsed in most of his cases to allow of a detailed analysis of the results, Dr. Mann was satisfied that it was a very valuable aid in the treatment of lung lesions requiring collapse therapy, its greatest use being in certain types of pulmonary fibrosis.

CLOSED DRAINAGE OF EMPYEMA.

Dr. J. D. McEACHERN followed with a paper on Closed Drainage in the Treatment of Empyema, including a report on 42 acute cases in infancy and childhood. The principles of modern treatment in this disease were: delay in operation, empyema not being looked upon as a surgical emergency; irrigation with Dakin's solution; and the application of negative pressure to assist in expanding the lung and thus obliterate the cavity. The closed method was slow in coming into general use, but after a personal experience in more than 50 cases Dr. McEachern had found this method so much better that he had abandoned the open method. The ages of his 42 patients ranged from 4 months to 11 years. One death occurred in the series, that of a child 14 months of age, who developed empyema after broncho-pneumonia. There was also one case of pleural shock during irrigation of the cavity by an inexperienced nurse. Except for two cases of pocketing, no case required secondary operation. The advantages of the closed over the open method were: (*a*) lessened mortality, attributed to the avoidance of general anæsthesia, the lessening both of surgical trauma and the danger of secondary infection; (*b*) lessened morbidity, the period of illness being reduced from an average of six weeks under the open method to 25 days. Another great advantage was the avoidance of the usual painful daily dressing.

PULMONARY LOBECTOMY.

The last paper of the session was contributed by Dr. N. S. SHENSTONE (Toronto) and Dr. R. M. JANES (Toronto) on Experiences in Pulmonary Lobectomy. This was based on seven cases in which one or more lobes of the lung had been removed for bronchiectasis —all of them having previously been treated for a long time by less drastic methods. No case was considered suitable for transfer to the surgical wards until lipiodol injections had, as far as possible, excluded bilateral or extensive multilobular disease. In each case the diaphragm was paralysed a few days before the major operation was undertaken. The technique adopted was modified from that originally described by Dr. Harold Brunn in his paper on One-stage Lobectomy. The reaction following operation was usually surprisingly slight, and primary union occurred in all wounds except one.

DISCUSSION.

A short discussion of the papers followed. Sir STCLAIR THOMSON spoke of some of his early experiences as house surgeon to Lister. Dr. L. S. T. BURRELL mentioned two points in regard to phrenic avulsion which he had found useful. The procedure was valuable in the case of moving mediastinum during treatment by artificial pneumothorax. He had himself found phrenic avulsion more efficacious in preventing this than the introduction of oil. The other great indication of phrenic avulsion was in terminating a prolonged period of artificial pneum- thorax. Dr. H. C. PARSONS spoke of the treatme of bronchiectasis in the Hospital for Sick Childre Toronto, by lipiodol with bronchoscopy, and postural treatment. Lord MOYNIHAN support Prof. Archibald's plea for specialisation, but dr attention to the danger of premature specialisatic The craft of surgery, he said, was now complete, b the bounds of surgery had not yet been approache

Mr. TUDOR EDWARDS said that there had be considerable variation in the attempts made remove diseased portions of the lung. He thoug that Dr. Shenstone had apparently made the interv between the stages of operation too long, but in a case the one-stage operation would probably be t method of choice in the future.

SECTION OF PATHOLOGY AND BACTERIOLOGY.

AT the first session of this Section the chair w taken by Prof. ROBERT MUIR (Glasgow), and discussion on the

Physiology and Pathology of Melanin

was opened by Prof. JAMES EWING (New York City Masson, he said, had brought evidence to show th melanomata were the result of a diseased conditi of the peripheral nervous system. His own observ tions had led him to agree with this contentio Examination of a deep subcutaneous nævus reveal the presence of special nævus cells, which appear to bear a similar relationship to the nerve-fibr entering the tumour as did the tactile corpuscles Paccini to the nerve-fibres of the skin. Nearer t epidermis there were also pigment cells, whi appeared to be derived from the nævus cells in t deeper layers. This structure led him to believe th the usual type of melanoma was essentially a tumo of nervous origin, and that the pigment was form not by epithelial cells, as was usually believed, b by cells that took origin in the peripheral nerv fibrils. It seemed that the pigment cells beca independent of the nævus cells, and were able certain circumstances to proliferate extensive In support of this he showed a lantern slide of tumour consisting purely of chromatophores; su tumours were met with in the dermis and in t epidermis as well as in the eye. In connexion wi the probable nervous origin of melanomata, it w interesting to note that nævi were frequently prese in cases of generalised neuro-fibromatosis, and th melanomata were not uncommonly of trauma origin. Although believing in the nervous origin nævi and melanomata, he would not go so far as rule out an epithelial origin; indeed he had one ca of a pigmented papilloma that undoubtedly originat in epithelium.

MELANOSIS COLI.

Prof. M. J. STEWART (Leeds) spoke chiefly melanosis coli—the condition in which there is deposition of melanin or melanin-like pigment in t mucous membrane of the large gut. His ov observations were based on two groups of cases: (*a*) unselected series of 600 autopsies, in which the wh length of the alimentary canal was subjected to care naked-eye examination, but in which only select examples were examined microscopically; (*b*) consecutive series of 100 cases of carcinoma of t colon, in which all cases were examined both mac and microscopically. In the first group 67 cas 11·2 per cent., of melanosis coli were detected mac

opically; in the second group 55, 55 per cent., were und macroscopically and 13 further cases micro- opically. The condition was rare under the age 30, and became increasingly common over 60. he importance played by obstruction in the causation melanosis coli was shown not only by the higher cidence in cases of carcinoma, but also by the fact at the pigmentation tended to be more intense above an below the growth. To the naked eye, the colour the affected mucosa ranged from greyish or buff ippling, through dark grey or brown, to intense ack. Pigmentation was almost always deepest in e cæcum and ascending colon, but in very advanced ses it might extend to the anus. Histologically, e pigment was generally confined to the mucosa, here it lay within the cytoplasm of large mononuclear lls. The epithelial cells, whether superficial or andular, were invariably free from pigment, and e solitary lymphoid follicles were usually so.

The exact nature of the pigment was not clear, but was probably intermediate between a melanin and lipofuscin. It differed from skin melanin in its ower solubility in antiformin, and in being bleached ss rapidly by hydrogen peroxide. Pick's theory the source of the pigment, which now met with neral acceptance, was that aromatic protein sintegration products absorbed from the large testine were converted into melanin within the nnective tissue cells by a tyrosinase-like ferment. is explained the importance of prolonged consti- tion as an ætiological factor, and the tendency for e pigment to be most intense in the cæcum and cending colon where absorption was greatest.

BIOLOGY AND BIOCHEMISTRY OF MELANIN.

Dr. SEYMOUR HADWEN (Toronto) spoke from the int of view of an animal pathologist. He believed at animals were coloured primarily for reasons nnected with their health. In Arctic animals the ange to white in the autumn was a structural ange and not a depigmentation. Trauma, the tes of insects, or bacterial action might result in an tensification of hair colour; on the other hand, they ight injure the cells so much as to prevent their oducing pigment. In horses, contrary to what was n in man, freckles became increasingly common th age. Old horses that lost their hair colour were nerally found to have melanotic tumours, and it med probable that in these cases the skin was ing robbed of the mother substance from which the lanin was made by the tumours themselves. As result the skin was unable to protect the sensitive sues below, and freckling might perhaps be regarded an attempt to bring about protection. In melanotic rses there was an excess of pigment in the epidermis certain parts of the body, resulting in disarrange- nt of the basal layers; there was no evidence, wever, that the surcharged cells descended into e dermis.

Prof. A. T. CAMERON (Winnipeg) discussed the chemistry of melanin production. The old view at hæmatin was a precursor of melanin had had to abandoned, though certain Italian workers still intained that melanin might be a pyrrole derivative. e of the difficulties in studying this subject was to termine whether melanin was a single entity, or ether it was merely a name used to designate stances of different chemical constitution. The tstanding contributions within recent years to the chemistry of melanin had been made by Prof. S. Raper, of Manchester University, and Prof. uno Bloch, of Zürich, the former of whom had idied the mechanism of production of melanin from tyrosine and the latter the action of dopa oxidase. It appeared probable that tyrosine was first oxidised by tyrosinase to dihydroxyphenylalanine—the so-called "dopa." This substance was then converted probably by a reaction involving dehydrogenation, to an indole derivative allied to tryptophane. By decarboxylation and a transfer of hydrogen atoms, dihydroxyindole resulted. Finally by a process of polymerisation melanin was formed. This substance had the alternative formulæ of $(C_8H_5O_3N)_n$ and $(C_8H_7O_3N)_n$, and was entirely free from sulphur or iron. It might be assumed that Bloch's dopa oxidase acted upon the tyrosine derivative dopa by the same mechanism as Raper's tyrosinase to give an identical melanin. Melanin had also been prepared from the urine of patients with secondary melanotic carcinoma of the liver, and from the nature of its preparation it was unusually pure. It was interesting to note that analysis of this urine melanin had given a figure for nitrogen very similar to that found for the melanin prepared by Raper from tyrosine. Examinations by Raper of melanins obtained from the skin of a negro, from the "ink" of the squid, and from a melanotic tumour showed no essential difference in constitution. It might be concluded, therefore, that many melanins were of almost identical structure.

The CHAIRMAN asked Prof. Ewing to define his views on the nature of the cells capable of forming melanin. He likewise drew attention to the extreme malignancy of the melanotic cell.

Prof. EWING, in reply, conceded that melanin might be produced by epithelial cells, but maintained that the nervous origin of melanomata was a view which offered the fewest difficulties in interpretation.

Prof. STEWART, in reply, said that melanomata were perhaps not so malignant as was generally supposed. The average length of life, after operation, of patients he had followed up was 2–4 years. He wished to draw attention to the importance of phagocytes in the transportation of melanin. The presence of melanin in lymphatic glands was not necessarily due to a melanotic metastasis, but might result from the transference of melanin from benign tumours.

Undulant Fever.

Prof. G. S. WILSON (London) read an occasional paper on the diagnosis of undulant fever, with particular reference to Great Britain. He remarked that infection with *Brucella abortus* might give rise to a number of conditions other than typical undulant fever, such as persistent malaise, obstinate headache, joint pains, abortion in women, and focal infections of the internal genital organs in men. In diagnosis the agglutination test was of great value, but its interpretation was often, a matter of considerable difficulty. Generally speaking, a titre of 1/80 or less, in the absence of clinical symptoms, was probably indicative of past infection. A titre of 1/100 or over in the absence of clinical symptoms was suggestive of a latent infection or of repeated past infections. A titre of 1/100 or over, in the presence of pyrexia or other symptoms of disease, was practically diagnostic of brucella infection. A titre of between 1/20 and 1/100, in the presence of typical undulant fever, might likewise be considered as practically diagnostic of infection. The complete absence of agglutinins from a patient's serum did not necessarily exclude the diagnosis of brucella infection. Blood culture was clearly the most satisfactory way of establishing a diagnosis, and every effort should be made to isolate the infecting organism from the blood. Though it was generally possible in *melitensis* infections to

obtain a positive blood culture, in *abortus* infections the percentage of positive results was much lower. Sometimes the infecting organism could be cultivated from other material, such as urine, fæces, or pus. Guinea-pig inoculation was not of great value, except in the examination of contaminated material. Finally, the intradermal reaction, at least in *melitensis* infections, had been reported on favourably by several observers, and its use on an extended scale deserved trial.

Extracts of Staphylococci.

Sir KENNETH GOADBY (London) read a paper on the fractional products of the staphylococcus. Owing to the irregularity of results in vaccine therapy, he had studied the properties of extracts of staphylococci made with water, alcohol, ether, and benzoyl chloride. The aqueous extract contained butyric acid, and substances that gave positive Fehling and Molisch reactions. The alcohol-ether extract contained lipoid-like bodies, which on injection into animals gave rise to an intense local reaction, simulating a carbuncle, though without suppuration. It was probable that the lipoid fraction of the organisms was responsible for the skin reaction in vaccine therapy, and he therefore advocated the use of staphylococci which had been previously treated with alcohol and ether.

Immunological Problems in Septicæmia.

Prof. WILLIAM BOYD took the chair at the second session of the Section, when Prof. FRED T. CADHAM (Winnipeg) opened a discussion on some immunological problems in septicæmia. He intended, he said, to refer to the type of case in which the symptoms of a general bacterial invasion overshadowed those of local origin, and in which chills, sweats, and irregular temperature were associated with the finding in the blood stream of the causative micro-organism—most frequently a streptococcus. In such cases the physician turned for help to the immunologist. The failure of the body to set up an adequate resistance to the invasion of a virulent bacterium might be due to a deficiency in antibody production, or to an imperfect utilisation of the antibodies by the tissue cells. In order to ascertain whether this second possibility was determined by the absence of complementary activity from the blood, he had investigated the amount of complement in health and disease. In the serum of 500 normal persons, complement, as titrated against sensitised sheep cells, was found to exhibit but slight variation. On the other hand, in an investigation of over 1000 patients suffering from different diseases, complement was observed to vary from an increase of 20 per cent. above normal to a complete absence. As a rule the onset of the symptoms of disease was attended by a slight increase in the amount of complement; this was followed by a steady decrease till the infection reached its maximum; while during convalescence a gradual return to normal occurred. The type of fluctuation depended on the disease from which the patient was suffering. In chronic diseases such as tuberculosis, syphilis, arthritis, goitre, diabetes, and uncomplicated malignant disease, only a slight oscillation occurred in the complementary titre of the serum. But in acute infectious diseases, particularly septicæmia, the fall in titre, following the initial rise, was rapid, and in fatal cases might proceed till it reached zero. From these observations he inferred that a high complementary titre in septicæmia was of considerable value in assisting the patient to overcome the infection. He had found that a patient's blood which was deficient in complement might be reactivated, in vitro and in viv by the addition of small amounts of normal serur the increase in complement that occurred lasted, a rule, for 2 to 3 days. In the treatment of septicæm therefore, he advocated the intravenous injecti of the patient every second day with about 30 40 c.cm. of normal serum from a compatible don On alternate days 2 to 5 c.cm. of serum, from a rabl immunised against numerous strains of streptoco and staphylococci, including if possible the particul strain isolated from the patient's blood, should injected subcutaneously. He had applied this meth of treatment to 56 patients suffering from septicæm and had obtained no fewer than 45 recoveries. It mu be admitted, however, that some cases of septicæm particularly those associated with destructive lesio in the brain or heart, were not likely to be benefit by serum therapy.

Prof. WILSON wished to know whether, in t titration of complement, allowance had been made f the natural anti-sheep hæmolysin present in hum serum. In view of the fairly marked variations fou by other workers in the normal complementa titre, he would like to see Prof. Cadham's actu figures, so that it might be possible to work out t standard deviation of the mean of each group, a the standard deviation of the difference between t means of the two groups of normal and diseas persons. Gunn's work did not altogether suppo Prof. Cadham's thesis, since he had found th complement in enteric fever and certain other diseas was generally raised during the pyrexial period, a might be present in large amount even just befo death. It was very difficult to interpret the meani of fluctuations in the complementary titre; a fall titre might be ascribed to diminished production complement, or to a combination of the existi complement with antibodies; unless the antibo titre was determined simultaneously, it was impossi to know which interpretation was correct. Our b results in passive immunisation had been obtain with antitoxic sera; there was less evidence that an bacterial sera were of any great value. Possibly t toxic bodies liberated by certain bacteria were no antigenic; this might account for our failure produce efficient anti-endotoxic sera. In conclusi Prof. Wilson pointed out that the results of any fo of treatment must ultimately be judged by statisti analysis.

Prof. OLIVER S. WAUGH (Winnipeg), speaking fro the clinical standpoint, testified to the value of Pr Cadham's work. Since extensive operations patients with septicæmia often did more harm th good, it was of great importance to do everything facilitate the early diagnosis of suppurative infectio which might lead to septicæmia. It was proba that much might be done by prophylactic vaccinati of patients about to undergo serious operations, su as removal of the rectum or the prostate.

Prof. ROBERT MUIR pointed out how difficult t was to obtain a clear idea of septicæmia. On th one hand there were cases, typified by enteric fev in which there was a simple overflow of organis into the blood from an infective focus; and on th other hand there were cases in which, with only minute lesion such as a pin-prick, the circulation w flooded with bacteria. All intermediate types case occurred. Phagocytosis played an import part in the actual destruction of micro-organis while antibodies were of great value in the establi ment of immunity. We knew nothing of the site complement formation, and the importance of a fa in complement was doubtful; such a fall might

cidental rather than essential. In assessing the lue of a given treatment it was necessary to submit e results to statistical examination; it was also of portance to observe the effect clinically, and he shed that clinicians would approach their cases th an open mind rather than obtain their cue from e bacteriologist.

Prof. CADHAM, in reply, agreed in the difficulty of fining septicæmia. He would not exclude the action complement in the toxin-antitoxin reaction.

Physiology of the Parathyroid Glands.

Prof. J. B. COLLIP (Montreal) gave a general review the physiology of the parathyroid glands. The nction of these glands, he said, was to act as a gulator of calcium metabolism, but the exact echanism by which the calcium in the circulating asma was kept constant was still unknown. The lcium content of normal human blood serum was 11 mg. per cent.; of this, not more than 2 mg. per nt. was in the ionised form, about 4·5 mg. per cent. as in organic, and the remainder in inorganic mbination. Calcium was of importance in the ilding up of the structural elements of bone and oth, in the clotting of blood, in the coagulation of lk, and in the regulation of neuro-muscular tone d irritability. This latter effect was probably due ionised calcium, and since changes in blood pH uld influence the degree of calcium ionisation, there ght be no essential difference between parathyroid tany due to a lowered calcium content of the blood d the tetany of over-ventilation, or of alkalosis, th of which were associated with a normal blood lcium but a diminution in the ionised fraction due an increased pH. The absorption of calcium from e alimentary canal was influenced by several ctors; the soluble chloride, lactate, or gluconate as more assimilable than the phosphate or carbonate. ie excretion of calcium occurred through the lower um and colon, and also through the kidney. There as a very close relationship between the metabolism calcium and of phosphorus, and it was as important determine the ratio between calcium and inorganic osphate in the blood as to estimate the actual ntent of either of these bodies. A rise in inorganic osphate led to a marked fall in the level of blood lcium.

Parathyroid hormone acted as a mobiliser of blood asma calcium; the source of the extra calcium was ne. Injection of this hormone into the dog led a rise in serum calcium, and if sufficient hormone as given marked hypercalcæmia developed, aracterised by anorexia, vomiting, diarrhœa, uscular weakness, respiratory distress, passing of ood by the bowel, bloody vomit, collapse, and death. man, chronic hypercalcæmia, due to increased tivity of the parathyroid glands, was seen in neralised osteitis fibrosa. Calcium metabolism as influenced not only by the parathyroid secretion, it by a number of other factors such as diet, acidosis, kalosis, exophthalmic goitre, and more particularly tamin D. Administered in excessive amounts to gs, vitamin D might produce fatal hypercalcæmia; is body was likewise able to relieve parathyroid tany, and to raise the serum calcium in the para-yroidectomised animal.

Prof. Collip then proceeded to discuss various inical conditions in which calcium metabolism or rathyroid function was disturbed. Chief amongst ese were post-operative tetany, infantile tetany, kalosis tetany, the tetany of spontaneous hypo-rathyroidism, osteomalacia, hunger osteopathy, and on Recklinghausen's disease.

PHYSIOLOGICAL AND CLINICAL FINDINGS.

Prof. V. H. K. MOORHOUSE (Winnipeg) discussed the subject from the physiological standpoint. We knew very little, he said, of the mechanism by which the parathyroid glands were stimulated, and it was not clear whether nerve impulses or chemical substances were responsible. Tetany in animals, following parathyroidectomy, was characteristically a nerve-muscle disturbance; in spite of an increase in the excitability, there was a definite lengthening of chronaxy. In experimental tetany convulsions were due to the effect on the nerve centres of the mid-brain. No relation had been found between changes in the irritability of the peripheral nerves and the severity of the convulsions; this might be ascribed to a general involvement of the nervous system.

Prof. J. C. MEAKINS (Winnipeg) dealt with the diseases in which there was a disordered calcium metabolism. He pointed out that only two of these conditions, namely hypoparathyroidism leading to tetany and hyperparathyroidism leading to von Recklinghausen's disease, were due to disease of the parathyroid glands. Speaking particularly of nephrosis, he remarked that, besides albuminuria and general anasarca, there was a decreased basal oxygen consumption and a lowered calcium content of the plasma. Yet tetany never developed in this disease; this might be due to a lowering of the phosphorus content or the pH of the blood. Cases of nephrosis with a low calcium plasma content often responded well to parathyroid therapy.

Dr. D. R. MCCULLAGH (Cleveland), discussing the treatment of post-operative parathyroid tetany, said that though the calcium content of the serum might be constant, the patient's condition was variable. In such cases he had found an increase in the phosphorus content of the serum. The interesting observation had been made that an increase in blood-sugar was accompanied by a fall in phosphorus. In conjunction with his brother, Dr. E. P. McCullagh, he had, therefore, treated a series of cases by lactose, a dose of about grs. 300 being given by the mouth each day. As a result the serum phosphorus had fallen, and the condition of the patients had improved greatly.

Prof. A. T. CAMERON (Winnipeg) considered the relation between parathyroid secretion and vitamin D as joint controllers of calcium metabolism. In young rats he had found that the normal calcium content of the serum was reached only at the height of summer, but that it was possible to produce a rise in the serum calcium by feeding them with irradiated ergosterol or irradiated food. There was no definite relationship between the quantity of vitamin D administered and the rise in the serum calcium; only a relatively small amount was required to maintain a constant level of calcium. Vitamin D might be the ultimate controller of calcium, acting perhaps through the parathyroid glands.

SOUTH LONDON HOSPITAL FOR WOMEN.—An extension of the out-patients' department which has cost £65,000, raised in three years by private contributions, was opened last week.

WEST SURREY CONTRIBUTORY SCHEME.—The first annual report of the West Surrey and Aldershot Hospital League shows that on Jan. 1st last there were 26,000 members, and that there are now 30,000. During the period reviewed £10,542 was received in small weekly sums, and the Royal Surrey Hospital has benefited to the extent of more than £4000 from this source. There are probabilities of a widening of the area of the League, which was founded in June, 1928.

PUBLIC HEALTH SERVICES

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1929 statistics of two districts which serve in varying degree as dormitories of London :—

Name of district and estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
West Ham C.B. .. (307,600)	18·7	12·7	1·12	1·22	3·2	1·8	74/—	50	2·6
Croydon C.B. (222,300)	15·3	12·5	0·89	1·48	3·2	1·4	65/26	25	3·2

Stillbirths per 100 live births : West Ham 3·4, Croydon 3·4.

West Ham.

Dr. F. Garland Collins says the housing problem, until solved, will continue to act as a check upon almost every other scheme for the promotion of the public health. He cites examples of overcrowding, typical of many others, to illustrate conditions prevailing. No municipal houses were erected during 1929.

The shortage of adequately trained nurses is becoming acute and rendered more so by the increasing number of persons seeking institutional treatment. In Dr. Collins's opinion the conditions of training, prospects, and remuneration of nurses and midwives should be investigated and revised. West Ham is a densely populated (67 persons to the acre) industrial area, as well as one of London's dormitories, with many large factories and a large dock area with resulting casual labour. During 1929 over 42 per cent. of the deaths of West Ham residents occurred in public institutions. Small-pox of the mild type continued through the year. There were 1277 notifications with three deaths, a male infant, a female 2 to 3 years, and a female 25 to 35. The small-pox hospital at Dagenham has been used for consumptives for years. In 1920 these patients had to be sent home when small-pox broke out. A similar tragedy of evacuating over 100 consumptives was averted in 1929, first by the agreement to send a limited number of small-pox cases to Orsett Hospital and subsequently by the timely action of the Metropolitan Asylums Board in admitting small-pox cases from West Ham. Dr. Collins refers to the vast amount of work entailed by this outbreak and thinks our methods of dealing with this mild type of small-pox might be modified with advantage. The fever hospital (210 beds) has the great advantage of a convalescent home at Harold Wood, about nine miles from the borough. At present there is accommodation there for 60 scarlet fever convalescents, who get the benefit of both natural and artificial sunlight. An extension is in progress of four 26-bed wards and four cubicles and should be ready for use next winter.

The Council have no maternity hospital but subsidise Queen Mary's Hospital, Stratford, and the Plaistow Maternity Hospital, in which 989 mothers were confined. There is much antenatal work. There are three clinics in connexion with the extern practice of the Plaistow Hospital, the midwives of which attended 3061 births. The two municipal antenatal clinics were well attended also, and a "follow up" system for the mothers attending was instituted in 1929 under which the health visito paid 3149 visits to 1890 expectant mothers. T births numbered 5766 and midwives, practisi privately or for associations, attended 4140 domicilia confinements and sent for medical help in 7 instances. A large number of women were al confined in the maternity block of the guardian The services of the municipal "home helps" we utilised by 876 mothers. In view of this extensi maternity service work the maternal mortality-ra of the last three years is interesting—viz., 3·0 p 1000 births in 1927, 2·1 in 1928, and 2·6 in 192

The veterinary officer, Mr. H. E. Bywater, repor that 38 per cent. of the cattle slaughtered and 3 per cent. of the pigs were affected with tuberculosi and that four cows giving tuberculous milk and tw with other signs were condemned under the ord as the result of periodical examination of 874 catt He suggests an amended nomenclature for grad milks—viz.: (1) tubercle free milk (i.e., from test herds—whether bottled on or off the farm); (2) clea milk (i.e., that now known as "Grade A"); (pasteurised milk. Mr. Bywater is also of opini from his experience that an appreciable proporti of the contamination of milk by tubercle is due to lac of cleanliness in milking and to the germ-lade atmosphere of the average cowshed.

Croydon.

Dr. Oscar M. Holden says the industrialisatio of Croydon makes rapid headway, and we must hav no repetition of the mistakes of the industrial revol tion. The influenza epidemic pressed most hardl on the old, and although the dry summer caused a increase in diarrhœa deaths of infants, the deat of children of 1 to 5 years were fewer than in 1928– 87 as compared with 96. There was a small outbrea of paratyphoid fever between the middle of Jun and the middle of August—37 cases of modera severity, but with no deaths. The cause of the ou break remained a puzzle, as the disease was n prevalent in contiguous areas at the time.

Housing conditions vary greatly though there is n large area of slums. Unsatisfactory and good are are often adjacent. An inspection of 4000 hous showed 6·6 per cent. overcrowded, using as a standa the minimum permissible for houses-let-in-lodgin under the by-laws. Under present legislation sul letting is the difficulty and a house suitable for o family may contain two or more. Houses which ca be let at not more than 10*s.* per week are the speci need. Over 16,000 gallons of milk is sold daily an 84 per cent. of it is bottled. Bottling is not necessaril a hygienic measure, Dr. Holden remarks, unless th milk put in is clean. The need for the examinatio of contacts of open cases of tuberculosis is not y properly appreciated in Croydon. The occupation scheme at the sanatorium, Cheam, has had a successf year under the guidance of the instructress, Miss M Goodman. Two orders for tapestry have kept a the women who could work busy since Easter. Th scheme has been extended to home work after dischar under the occasional supervision of the instructres who arranges for the sale of the finished article Some of the men continue at home the leather wo learnt in the sanatorium and find their own marke A window at the dispensary is used as an exhibit advertise Cheam products. Such a scheme does n pay expenses but it makes hours, which might l spent in idling or harmful introspection, interestin and profitable, and a hobby is doubly valuable to th tuberculous. There is a decrease in the new cases the V.D. clinic but a satisfactory increase in th number of attendances. The nursery for ailing babi and children up to 5 years has been kept full occupied. It nominally has accommodation f 14 babies and 2 nursing mothers, but the demand wou justify extension. Ten mothers and 77 babies we

mitted during 1929—the babies chiefly for alimen-
y disorders, failure to thrive, re-establishment of
east-feeding, mismanagement, and so on.
In April the Council established a small home for
low-grade mentally deficient boys under 16.
e difficulty in finding institutions for the mentally
ficient has been accentuated by notice from the
tropolitan Asylums Board to remove 30 Croydon
tients. It is hoped to carry out a joint scheme with
County Council for additional accommodation.

EPORTS OF SCHOOL MEDICAL OFFICERS.

—	No. on roll.	Average attend-ance.	Routine inspec-tion.	Special exams. and reinspec-tions.	Percentage of defects.
thampton	12,557	11,219	4,398	10,788	11·8
ckport ..	15,088	13,330	5,198	12,315	26·7
gan ..	13,459	12,020	4,116	8,654	24·8

Northampton.

Dr. Stephen Rowland says the outstanding circum-
nce connected with the service during the year was
continued presence of small-pox in the town since
ly, 1928. There were 112 children of school age
tified, most of the cases being of the prevalent
ld type liable to be mistaken for chicken-pox.
ne of the children had been vaccinated before
posure to infection. Less than 20 per cent. of all
children in the town from 4 to 7 are, in fact,
tected, although the proportion is higher than it
s last year. In 13 departments there was undoubted
ss infection, but it was not found difficult of
ntrol. It was not considered advisable to close
y school, the scheme in operation being found to
rk satisfactorily, though it involved much additional
rk for the assistant medical officers, so that there
re 600 less routine medical inspections this year.
e period between routine dental inspections has
come nearly three years instead of 12 months.
ntal treatment has the excellent record of 2511
es dealt with out of 2667 found to require treat-
nt. Similarly, the results with medical and
gical defects are highly satisfactory, 93 per cent.
ving obtained treatment. The scheme of operation
tonsils and adenoids is working smoothly, and
. Rowland regards this as important, for he is
nvinced that, whatever may be said to the contrary
the lay press against it, nothing short of operation
l be of avail in cases such as those seen at the
ectious diseases hospital.

Stockport.

Dr. N. Gebbie is able to report substantial progress
l a definite prospect of improved facilities. The
w school at Belmont, opened in August, 1929,
rks a step forward in the provision of modern
commodation; in some older buildings the heating
tallation, whose failure necessitated closing for
few days in the winter, has been overhauled.
uctural alterations to be made at the clinic will
ist the dental work, for even with two full-time
ntists and assistance it has been found impossible
carry on with one surgery. Dr. Gebbie pays a
bute to the retiring dentist, Mrs. Sibson, for her
ll and popularity. Parents, he says, have begun
realise more fully the importance of having their
ldren's teeth more properly cared for, and he looks
ward to the time when the system of inspection
l treatment will cover all the children. A large
mber of children (511) are regarded as suitable for
open-air school, and a site with ideal position and
vironment has now been bought. For other
eptional children facilities have been wanting—
re are no day special schools of any kind—but
orts to find places for them in residential schools
ve been unusually successful. In most of the groups
substantial number of cases have been properly
lt with in spite of the difficulties; with the epileptic
re is not only the difficulty of finding accommodation
but the greater obstacle of parents' refusal. Numerous voluntary agencies provide spectacles, surgical apparatus, clogs, convalescence, holidays, Christmas presents, and treats. An object of legitimate pride is the stammering class, the results of which are very promising.

Wigan.

Dr. H. Whitehead reports progress in several directions, and shows the need for more. An approved scheme for orthopædic treatment began at the end of 1927. By arrangement with the county council a special nurse attends every week at the central clinic and an orthopædic surgeon once a month. Cases for hospital treatment are sent to the Biddulph Hospital, Staffs., a fine up-to-date institution under the control of the Lancashire County Council; but the reservation of three beds does not seem large for a town of the size of Wigan. Twenty-six cases of rickets and 50 other deformities were discovered in 1929; many of these, Dr. Whitehead says, would benefit considerably at a special school or by special exercises; but he makes no note of such facilities, and apparently none exist. It is in dental work that most has been done. In September, 1928, a full-time dentist was appointed, assisted by a full-time dental nurse who visits unwilling parents; but there are still 20 per cent. who refuse treatment altogether. It is thought that improvement would follow if head teachers impressed on the children the importance of having the teeth attended to, and insisted on the consent form being returned. There are, it seems, some teachers who take a great interest in the teeth of the school-children and at their schools far more consents are given. In securing treatment for visual defect, too, Dr. Whitehead solicits more help from the teachers. Artificial sunlight treatment has yielded some good results, but attendances are irregular; treatment is given at the infirmary, a long way from many of the homes. The work done at the school clinic is badly handicapped by the inadequate building. By thorough remodelling the school at Warrington-lane has been taken off the black list of the Board of Education. One of the greatest needs of the town, Dr. Whitehead says, is an open-air school, for some 1200 children under 12 years of age are exposed to massive infection by tubercle in their homes. Such schools are badly needed in industrial towns, and no form of expenditure yields a better return for money spent. It is good news that a nursery school is to be started in the present year.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 30TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 99 (last week 93); scarlet fever, 1441; diphtheria, 923; enteric fever, 70; pneumonia, 376; puerperal fever, 29; puerperal pyrexia, 95; cerebro-spinal fever, 11; acute poliomyelitis, 23; acute polio-encephalitis, 5; encephalitis lethargica, 9; dysentery, 7; ophthalmia neonatorum, 99. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Sept. 2nd–3rd was as follows:—Small-pox, 209 under treatment, 5 under observation (last week 209 and 4 respectively); scarlet fever, 1548; diphtheria, 1718; enteric fever, 33; measles, 146; whooping-cough, 87; puerperal fever, 23 (plus 11 babies); encephalitis lethargica, 119; "other diseases," 22. At St. Margaret's Hospital there were 14 babies (plus 8 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 4 (2) from enteric fever, 7 (1) from measles, 6 (1) from scarlet fever, 13 (2) from whooping-cough, 21 (4) from diphtheria, 52 (16) from diarrhœa and enteritis under two years, and 17 (3) from influenza. The figures in parentheses are those for London itself.

The deaths from enteric fever outside London occurred at Willesden and Sunderland. Leeds reported 2 deaths from

whooping-cough; Liverpool and Manchester each 2 from diphtheria. Diarrhœa was responsible for 11 deaths at Liverpool, 3 at Birmingham, and 2 each at Enfield, Wigan, and Salford.

The number of stillbirths notified during the week was 285 (corresponding to a rate of 43 per 1000 births), including 42 in London.

DEATH FROM SMALL-POX.

The death from small-pox reported from Wallasey during the week ended July 26th was that of a patient, aged 34, infected whilst residing in Wallas by a mild unrecognised case which was not unc treatment. Vaccination had been done in infan but only showed a faint mark. The illness develop acutely and was of a hæmorrhagic and toxic ty The patient was removed to the Liverpool P Isolation Hospital on July 19th and died on the 23 Dr. W. Hanna, medical officer of health for Liverpo informs us that there has been no spread of t infection, no doubt as a result of prompt vaccinati or revaccination and supervision of contacts.

CORRESPONDENCE

TREATMENT OF PULMONARY TUBERCULOSIS IN SWITZERLAND.

To the Editor of THE LANCET.

SIR,—As physicians who have been residing and practising in Switzerland for many years, and who are especially interested in the treatment of pulmonary tuberculosis amongst English patients, we wish to protest very strongly against the mischievous letter which appeared in THE LANCET of August 9th (p. 315) over the signature M. G. Davis.

In the first place, Dr. Davis's facts are entirely wrong. The "tourist" industry of Switzerland is not by any means its principal one, but comes fourth or fifth. There is no doubt, however, that the art of making guests comfortable and well looked after is highly developed in this country. This is also the case in Swiss sanatoria, but the puerile remarks, that in sanatoria patients suffering from pulmonary tuberculosis are induced to go to dances and cinemas against their wish, are utterly untrue and too absurd to be discussed.

Switzerland has been well known for very many years for the successful treatment of tuberculosis of the lungs. People come to this country—often after treatment somewhere else without much benefit—not only from England, but from all parts of the world, and England after all supplies but a very small percentage of the patients. Looking at it from a purely business point of view, Switzerland must be able, then, to obtain for them what they come for—i.e., an arrest of their disease. If this were not the case patients would not have come to the Swiss mountains in increasing numbers for the last 70 years, and the Swiss themselves would not have built their cantonal sanatoria for the treatment of pulmonary and surgical tuberculosis on so large a scale in the various high altitude stations at their disposal. Their example has been followed by foreign countries—e.g., Germany, Holland, Belgium, Greece, Hungary—and it is much to be regretted that England gave up the Queen Alexandra Sanatorium in Davos.

Patients come to Switzerland for treatment of pulmonary and other forms of tuberculosis because the country can offer a climate in which it is pleasurable to remain out of doors, even for those unable to take much exercise. The dry, wind-free, and sunny climate of the high altitude stations undoubtedly is a factor which England cannot provide. The Swiss sanatoria are admirably run, and the medical men superintending them are scientifically to the front. The sanatoria possess absolutely modern installations.

We are afraid that Dr. Davis's statements are not based on personal experiences, but are uncontrolled repetitions of small talk.—We are, Sir, yours faithfully,

ED. NEUMANN, M.D.,
Med. Supt., Schatzalp Sanatorium, Davos.
BERNARD HUDSON, M.D., M.R.C.P.,
Sept. 1st, 1930. Davos.

To the Editor of THE LANCET.

SIR,—May I give you the experiences of a pati of mine? I think you will agree that the patient at least an interested party.

"A few years ago," she writes, "I entered a go private sanatorium in England as a patient. I pa £7 7*s.* a week and extras. During the first two mon of my stay there it rained (literally) every day. I shall never forget the misery of the daily walks pouring rain, the return with sodden boots a clothes, the shivering changing in a half-warm room, the damp pouring in at the wide-open windo (envelopes kept in the drawer of a desk always stu themselves down!), and the miserable dashes o meals—the dining-room being a building stand isolated in the grounds—under an umbrella, with consequent necessity of always wearing old cloth a depressing thing to a woman! I wish that y doctor correspondent who talks of the chances England of nature study could have been there. should like to have seen him studying the m And, then, the awful gloom! Bed-patients la often in rooms on the ground floor—watching rain falling on the wet lawn; for the sanatori stood in large grounds, was right in the heart of country, and the road was not visible from windows. The 'closed-in' feeling, *in England,* appalling. All the women cried when they w alone. We admitted that to one another. And th were rumours about the men crying too.

"Certain private business compelled me to cur my 'cure,' and I left the sanatorium. The busin completed I tried once more, and this time went a sanatorium in Switzerland. I paid the equival of £7 7*s.* a week in the summer and extras, and £8 a week in the winter and extras. And, oh! difference. The first thing I noticed was the *ligh* Switzerland as opposed to the awful gloom in Engla the exhilarating feeling of being no longer 'closed for from my window I could see for miles along over the river valley. I revelled in the glory of ever-changing view, the sunrises (if I couldn't sl and the sunsets, and in winter the fascination of ever-changing snow line. I know that the sun the loveliness and the air helped me happily thro a year of bed. And when I got up, no mud, no glo but fields of gentians and primulas, the pleasant of chats with patients from other sanatoria at vill cafés, and playful rivalry as to who was at the sanatorium, and what was happening at each. England the villagers had viewed us with alar And in winter the fun of watching sports and so feeling of participating, to however small an ext in the life of normal folk, instead of the terr feeling of isolation which is, I think, the har thing the tuberculous patient has to bear. sanatorium that I went to in Switzerland tried be a hotel *for the sick;* the one in England—run

most estimable people, I try to believe—was never anything but an institution. In it I know that my spirit was never free."

She adds: "I have been quite well for years and intend to remain so, but I can't help thinking of the other folk." I am, Sir, yours faithfully,

Sept. 3rd, 1930. M.R.C.S.

To the Editor of THE LANCET.

SIR,—Before you close the correspondence following on Dr. Harrison's article, will you allow me to refer to two excellent articles which appeared in your columns a few years ago: (1) Notes on the Value of Swiss Sanatorium Treatment (THE LANCET, 1926, ii., 580), by Dr. Alex Sandison, who had unrivalled opportunities of comparing English and Swiss treatment in the case of Ministry of Pensions patients. After weighing the relative advantages and disadvantages of Switzerland, he came to the conclusion that there are no grounds for the alleged superiority of Switzerland over other places. (2) Can as good Results be obtained by the Treatment of Pulmonary Tuberculosis in the Lowlands as at High Altitudes? (THE LANCET, 1912, i., 1127), by the late Prof. C. Saugman, who showed, as far as statistics can show anything, that the results of treatment close to sea-level are distinctly better than those obtained in the high Alps.

Saugman compared the results obtained over a period of 12 years at his Danish Sanatorium of Vejlefjord, 25 metres above sea-level, with a long series of results obtained at Turban's Sanatorium, Davos, a few years previously at an altitude of 1573 metres above the sea. The results were in favour of the low altitude. For example, taking stage I and stage II cases, those who lost their tubercle bacilli were 72 per cent. in Denmark, against 57·5 per cent. in the high Alps. Again, those admitted with fever who lost their fever by the end of their period of treatment at the sanatorium in the stage II cases were 96 per cent. in Vejlefjord and 80 per cent. in the Alps; in stage III cases 69 per cent. against 44 per cent. Further, those able to work after a period of one to seven years from the time of their leaving the sanatorium in the high Alps, and two to 10¾ years after leaving Vejlefjord, were as follows: In stage I the proportion of patients from Switzerland able to work was 3·3 per cent. higher. But in stage II the percentage was 71 for Danish patients, against 54 for the high Alps; and in stage III, 24·7 for the Danish, against 16·8 for the Alpine ex-patients. These results were in spite of the fact that the average stay in Turban's Sanatorium was 222 days, against 176 days at Vejlefjord.

I am glad Dr. Savy points out in your last issue that the total hours of bright unclouded sunshine at many places in our own isles is little different from the number in the Alps—indeed sometimes higher. For example, the total hours at Lowestoft last year were 1808 hours, and the average there for the 30 years ending 1910 was 1727 hours (see Sir Leonard Hill's "Sunshine and Open Air," p. 46). On comparison with Maurer and Billwiller's "Das Klima der Schweiz," one finds that Lowestoft generally gets rather over half an hour a day more bright unclouded sunshine than Leysin, given as 4·25 hours per diem on the average of the year, and only about seven minutes less than Davos and Arosa.

One further reference. In his address at Portsmouth three months ago before the congress of the Royal Institute of Public Health (see the *Times*, June 6th), Sir Henry Gauvain said that sun treatment for its general effects, especially in surgical tuberculosis, is more effective in his estimation in the constantly changing conditions which are found in the temperate climate of England.

I am, Sir, yours faithfully,

Mundesley, Sept. 7th, 1930. S. VERE PEARSON.

THE MEDICAL TREATMENT OF CANCER.

To the Editor of THE LANCET.

SIR,—In my earlier publications due reference has been made to Prof. Blair Bell's pioneer work. As the time passes I feel the less inclined to be bracketed with him for many reasons, the chief one being that the evidence accumulates to show that the lead ion has only a secondary rôle in the treatment which we use; in fact we have great hopes that this dissentient metal will shortly be eliminated from the treatment altogether. At present we consider the ion lead simply as a vehicle for selenium. Within a week of the publication of my first provisional announcement, Prof. Blair Bell wrote to say that his chemists had had no difficulty in making lead selenide. As I had very carefully gone through his writings and found no reference to selenium, I wrote to him and asked him to contradict publicly an impression of priority which his letter would cause. This he did, and this constitutes the correspondence to which he makes allusion. Now Prof. Blair Bell repeats the programme. From his letter with its hints of correspondence and supervision he would give the impression that the whole method has been taken from him. The system as described has been originated here from the work of others and ourselves, and owes nothing more to him.

I should like to congratulate Dr. P. Gosse and Dr. J. C. Mottram on the result of combination of radiation and selenide, and I hope they will be able to supplement the list considerably in the near future. The details requested were published, at least in some of the cases, as was noted in reference 3 of my paper. In the remaining cases the dosage of radium, radon or deep X rays was the half of what that growth would have been given if radiation had been the only treatment proposed. In all, the radiation was given concurrently with selenide, or the latter was stopped when radiation was started. In view of these bad results and the steadily increasing use of D4S, as shown by the sale figures of British Drug Houses, Ltd., I considered that a warning ought to be issued. I have repeatedly pointed out that this apparent adverse action is to be attributed to the selenium, for radiation after lead guaiacolate does not appear to be deleterious.[1]

I should have thought that my article was in favour of the combination of selenide and radiation therapy; perhaps Drs. Gosse and Mottram will read it again. I am employing the two concurrently in an increasing number of cases, and so far have reason to be pleased with the results. Perhaps a brief account of a recent case may be of interest; it is chosen from several, full accounts of which will probably appear when proof is regarded as adequate.

A girl, aged 25, had her leg amputated through the upper third of the femur for periosteal sarcoma of the tibia. This was followed by recurrence in the femoral stump, and she was referred to me about a year ago. She was treated by the method we have evolved in Bristol, but growth continued slowly, and in June of this year she appeared to be dying; she was much emaciated, had much pain, suffered much from cough and dysphagia. A skiagram showed her lungs and mediastinum to be riddled with large metastases. I then changed her treatment to a selenide not of lead, at present in the experimental stage, and asked for concurrent radiation. A trial dose of deep X rays, one eighth of the carcinoma dose, was followed by slight alteration of the blister leucocyte count; therefore she was given this eighth dose twice weekly, alternately to chest and stump; the selenide was given weekly. I expected that she would not be alive when I returned from holiday early in August, but found her very much better. She had put on weight, lost dysphagia and cough, and another skiagram showed considerable diminution

[1] Brit. Med. Jour., 1929, ii., 325; THE LANCET, 1930, i., 906; and ii., 389.

of the pulmonary masses. I should here record my thanks to Dr. Mayes and the radiological staff of the Bristol Royal Infirmary for their help in this work.

I hope that Drs. Gosse and Mottram will continue their researches, for this aspect of the problem—the combination of selenide and radiation—requires more time than I can give, and a knowledge of radiation to which I cannot lay a claim.

I am, Sir, yours faithfully,

Bristol, Sept. 8th, 1930. A. T. TODD.

PATHOLOGY OF DIABETES.

To the Editor of THE LANCET.

SIR,—Just 25 years ago, in my Goulstonian Lectures (published in your columns [1]), I suggested that diabetes mellitus was a disorder of fat-metabolism, associated with some defect of the pancreas. I gather from Prof. J. J. R. Macleod's Oliver-Sharpey Lectures that all we now know is that diabetes is due to lack of insulin, and that much, at all events, of the sugar comes from fat. May I claim to have made at least an intelligent anticipation of the state of pathological theory a quarter of a century ahead?

I am, Sir, yours faithfully,

WM. CECIL BOSANQUET.

Nottingham-place, W., Sept. 6th, 1930.

LONDON RUBBISH.

To the Editor of THE LANCET.

SIR,—Your leading article is timely. I think it is high time someone drew the attention of the public to the defects in our sanitary services. In the neighbourhood in which I reside the household refuse is left outside the houses for collection in buckets, generally without covers, or without being covered. Owing to their small size they are usually filled to overflowing, this resulting in their contents being blown about the streets. Between 8 and 10.30 A.M. an open lorry appears and the contents of the buckets are chucked anyhow into it with the maximum of noise and clatter. The lorry is gradually filled, also to overflowing, some of the contents of the buckets are distributed about the streets in the process of being emptied, and the streets are further defiled as the lorry jolts along, especially if there is any wind.

We are entitled to be relieved from these insanitary and unsightly methods of refuse removal in view of the enormous expense we are put to for the provision of sanitary services. We should have up-to-date covered wagons, designed to obviate leakage when loading or moving about the streets. These can be seen in quite small continental towns. It should be compulsory for the householder to provide adequate receptacles of standard pattern, and they should be covered when outside the house. The men who carry out the duties should be provided with clean overalls or smocks, and encouraged to keep themselves as clean as may be.

The above-mentioned defects are not peculiar to the neighbourhood in which I live, for one day last autumn at 4.15 P.M. I had part of the contents of one of these dreadfully insanitary open lorries blown into my face—and this in a street overburdened with experts in sanitary science.

I am, Sir, yours faithfully,

LEONARD MOLLOY.

Harley-street, W., Sept. 6th, 1930.

[1] THE LANCET, 1905, i., 903, 977, 1053.

OBITUARY

LEONARD PORTAL MARK, M.D. Brux., M.R.C.S. Eng.

THE death of Dr. Leonard Mark on Sept. 5th, a his house in Oxford-terrace, brings to an end career which combined medicine and art in th service of his fellows. Leonard Portal Mark wa born at Marseilles in 1855, the second son of Edwar Wallhouse Mark, who was at that time British Consu there. He was educated in France which gave hi the lifelong advantage of being bilingual, and entere St. Bartholomew's Hospital from which he qualifie M.R.C.S. in 1879, and L.R.C.P., L.S.A. in 188 He held house appointments at the Sussex Count Hospital, the Richmond Hospital, the General Lying in Hospital at Lambeth, and the Bethlem Roy Hospital, thus obtaining an all-round experience disease. He then settled in Paddington where h gradually built up a considerable general practic but his heart was in his artistic work, and after havir made a hobby of etching he was appointed pathologic artist at St. Bartholomew's Hospital. Although practised hand at depicting the evidences of disea in others, it is a curious fact that he had borne himse for 13 years the facies of acromegaly before becomin aware of it. "Each day," he wrote in his aut biographical study, "when I looked into the gla to brush my hair, there was a typical acromegal literally staring me in the face. Yet I nev recognised the fact." It was in 1892, he tells u in the ABC shop in Little Britain to which Bart. men then resorted, that he told Sir Archibald Garr of his increasing effort to make his jaws meet. Garro who already knew of Mark's eye symptoms, made th diagnosis, but kept it to himself. In Novembe 1905, Mark was crossing Cavendish-square wh the self-revelation came, and on returning home four his own condition described in Bowlby's "Pathology Although the disease took its usual course wi severe headache and increasing disability, th philosopher in Mark transcended the patient, and h not only published his personal experience of th disease, but contributed to our own columns a stud of Richard Dickinson of Scarborough, shoe-clean and gingerbread vendor, whose portraits by sev contemporary artists betray the stigmata acromegaly. The 1726 portrait of Dickinson probably the first representation of acromegaly to b found in this country, although earlier ones we recognised on the continent. Some acromegal features Mark found too in the physiognomy a temper of the Punchinello of our street show. Ma bore his sufferings with great courage, and it gratifi his friends to know that his headaches became le severe as he became more infirm. He was caref to preserve a series of photographs to serve as a reco of the progress of his disease. Apart from his writin on acromegaly he collaborated in the translation Pozzi's "Gynæcology" in three volumes issued b the New Sydenham Society. He was at one tim President of the West London Medico-Chirurgic Society, and Vice-President of the Harveian Societ

"THE ROYAL PLYMOUTH HOSPITAL."—Th governors and subscribers of the Central Hospit Plymouth, have agreed, in principle, to the amalgamati of that institution with the South Devon and East Cornw and Royal Albert Hospitals under the style of "The Roy Plymouth Hospital." The object is coöperation a coördination.

MEDICAL NEWS

National Council for Mental Hygiene.

A series of lecture-discussions has been arranged by this Council, and will be held at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., at 5.15 P.M. on certain Thursdays in October and November. Dr. G. W. B. James will start the course with a lecture entitled a Physician Looks at History (Oct. 16th); Dr. Alice Hutchison will speak on Preventive Treatment in Childhood (Oct. 23rd); Dr. Edward Mapother on Alcoholism and Drug Addiction (Oct. 30th); Prof. William Brown on Mental Conflict and the Development of Character (Nov. 13th); Dr. Doris Odlum on the Psychology of Adolescence (Nov. 20th); and Dr. R. G. Gordon on the Importance of Mental Deficiency (Nov. 27th). Tickets are obtainable from the Secretary of the Council, 78, Chandos House, Palmer-street, S.W. 1, or at the doors.

The second Mental Health Conference organised by the Council will be held in May, 1931.

A Faculty of Medicine for Marseilles.

The premier seaport town of Marseilles, which is already the seat of a medical school, is to become endowed with a regularly constituted medical faculty. This result has only been attained by slow degrees, for the establishment of the faculty was for long held in suspense. The site and various parts of this new institution is to be the Pharo Palace, which was constructed on behalf of the late Empress Eugénie. The chateau is attractively situated, overlooking the sea.

Lectures on Medical Hydrology.

The Committee for the Study of Medical Hydrology is arranging its programme for the coming winter. The object of the Committee is to supply lecturers, on the subjects of spa treatment and general medical hydrology, for medical societies and for medical schools where these subjects are not already included in the curriculum. A list of the lecturers available will be forwarded on application to Dr. Geoffrey Holmes, 11, Ripon-road, Harrogate.

International Society of Medical Hydrology.

The annual meeting of this society is being held this year in Lisbon and the Portuguese spas, from Oct. 15th-23rd, in conjunction with the Congrès international d'Hydrologie. One medical discussion is being arranged by the Society, on the Treatment of Digestive Disorders by Waters and Baths. General meetings will also be held to consider a system for the international registration and classification of waters, the organisation of health resorts for insured workers (social hydrology), and proposals for the protection of the names of the spas. The Portuguese spas to be visited include Coimbra, Curia, Oporto, Bussaco, and Vidago. The meeting is open to non-members and a limited number of medical practitioners and students interested in hydrology are invited to take part. Applications should be received at the office of the Society, 55, Wellington-road, London, N.W. 8, not later than Sept. 15th. The journey to Portugal may be made by sea from Boulogne, or overland.

Donations and Bequests.

Mr. W. J. R. Pochin, of Wigston, Leicestershire, left £1200 to the Leicester, Leicestershire, and Rutland Institution for the Blind.—Miss E. E. Oates, of South Royde, Halifax, Yorks, left £1000 to the Royal Halifax Infirmary.—Mrs. I. N. Whipp, of St. Annes-on-the-Sea, who left £12,269, left £500 in trust for the relief of the poor of Clitheroe, £300 to the Cripples' Home, Strangeways, Manchester, £200 to St. Mary's Hospital, Manchester, and one-third of the residue of the property to the Blackburn Infirmary.—Elizabeth Lady Smiley, of Park-street, London, W., Forest House, Bournemouth, and Larne, Co. Antrim, among other bequests left £3000 to the Smiley Cottage Hospital, Larne, Co. Antrim, £5000 to the Royal Victoria Hospital, Belfast, £6400 to the Royal Alexandra Infirmary, Paisley, and £5000 to the Hugh Smiley Day Nursery, Paisley.—Mr. Joseph Watson, of Bramhall, left £1000 each to the Salford Royal Hospital, the Manchester Royal Infirmary and Dispensary, and the Ancoats Hospital and Dispensary; also £500 each to the Coal Smoke Abatement Society, Manchester, and the Northern Counties Hospital for Incurables, Mauldeth.—Fleet Surgeon A. T. Corrie, R.N. (retd.), Plymouth, left £32,473. He gave £1000 each to the Cripple Home for Boys at Kensington, the Royal United Service Orphan Home for Girls, Devonport, and the Orphan Home for Girls at Lockyer-street, Plymouth; and £500 to the Corporation Grammar School, Plymouth. After a personal bequest of £1000 he left the residue of the property to St. Bartholomew's Hospital.

Lectures in Tropical Hygiene and Nursing.

The County of London Branch of the British Red Cross Society (27, Grosvenor-place, S.W.1.), has arranged a course of nine lectures and demonstrations on Tropical Hygiene and Nursing, to be given at 8 P.M., on Wednesdays, from Oct. 1st, at 27, Grosvenor-place.

Middlesex Hospital Medical School.

Mr. Eric Pearce Gould will give the introductory address when the ninety-sixth winter session of this school opens at the Queen's Hall, Langham-place, on Wednesday, Oct. 1st. Mr. Arthur Greenwood, the Minister of Health, will take the chair at 3 P.M., and distribute prizes gained during the past year. After the ceremony the wards of the new west wing, the new nurses' home, the medical school, and the research department will be open for inspection.

Queen's Hospital for Children.

Last year new out-patients (30,806) showed a reduction of about 4000 which the annual report attributes to the continued improvement in public health organisation. Each out-patient cost 6*s*. 3*d*. There were 1969 in-patients who cost £12 13*s*. 7*d*. each. The income was £34,998, and the expenditure £33,135. A debt of nearly £10,000 has been reduced to £3225, and the hospital has paid its way since 1924, but money for extensions is now needed.

Royal Sanitary Institute.

Dr. G. F. Buchan will preside over a sessional meeting of this Institute, to be held at Hereford on Saturday, Oct. 4th. The Mayor (Mrs. Luard) will open a discussion on the Place of Women in Local Government, Mr. G. H. Jack, F.R.I.B.A., on the Preservation of the Countryside, and Mr. J. R. Barker, M.R.C.V.S., on the Health Authority and the Milk Supply.—At a sessional meeting at Nottingham on Friday, Oct. 10th, Mr. A. R. Atkey will speak on River Pollution, and Dr. L. P. Lockhart will open a discussion on Industrial Medicine in Relation to Public Health. Dr. Charles Porter will take the chair.

Paddington Medical Society.

At a meeting of this society held at the Great Western Hotel on Sept. 9th, Dr. E. G. Graham Little, M.P., spoke of the imminence of a scheme for a State medical service, and of the drawback to extension of contract medical practice on existing lines. Mr. E. B. Turner said that while medical benefit under the Insurance Act was working well in rural districts, the situation was different in urban districts where there were rumblings of a coming storm. In the discussion which followed attention was called to the increase of voluntary contract practice in the work of the London Public Medical Service, and to the need for those actually engaged in practice to make their views effectively known.

Royal Institute of Public Health.

The Harben lectures for 1930 will be given at this Institute by Prof. William H. Park, of New York, at 4 P.M. on Oct. 6th, 7th, and 8th. His general subject will be Pneumonia, and the three lectures have the following titles: (1) the Types of Pneumococci in Adults and Children and Their Significance; (2) the Epidemiology; the Refining of Anti-pneumococcus Serum; (3) the Therapeutic Use of Vaccines and Antibacterial Sera.—The address of the Institute is 37, Russell-square, London, W.C. 1, and no ticket of admission is required.

A course of lectures on the Prevention of Accidents, Disorders, and Diseases, is to be given at the Institute at 4 P.M. on Wednesdays from Oct. 15th. The speakers will be Dr. E. Graham Little, M.P., on the Prevention of Accidents, Disorders, and Disease in Members of the Medical and Nursing Professions (Oct. 15th); Prof. W. S. Lazarus-Barlow, M.D., on the Prevention of Pre-cancerous States and the Arrest of Cancer (Oct. 22nd); Lieut.-Colonel J. A. A. Pickard on the Prevention of Street Accidents (Oct. 28th); Prof. S. Lyle Cummins, M.D., on the Prevention of Tuberculosis (Nov. 5th); Dr. R. Stenhouse Williams on the Importance of a Complete Study of the Nutritional Value of Milk (Nov. 12th); Dr. Arthur Massey on the Prevention of Venereal Disease (Nov. 19th); Mr. Leonard Ward on the Prevention of Accidents in Factories and Workshops (Nov. 26th), Prof. D. B. Blacklock, M.D., on the Prevention of Disorders and Diseases in Tropical Countries (Dec. 3rd); Sir Hubert Bond, M.D., on the Prevention of Mental Illness (Dec. 10th); and Prof. E. L. Collis, M.D., on the Prevention of Industrial Diseases (Dec. 17th).

Royal Waterloo Hospital.

Last year out-patients' attendances increased from 56,000 to nearly 70,000, and the department will have to be further extended, but the cost of land in the vicinity of the hospital makes the problem difficult. The surplus of income over expenditure was used to reduce the accumulated deficits, which now stand at £2797.

West Kent Hospital.

The ninety-seventh annual report of the West Kent General Hospital, Maidstone, shows that last year there were 1251 in-patients who cost 10*s.* 5*d.* per day and stayed an average of 23·3 days. Including casualties there were 9899 new out-patients. The cost per occupied bed was £190 1*s.* 9*d.* There are 102 beds, 8 of them for paying patients. The Pay Day Fund provided the hospital with £3746. Extensions costing over £50,000 are in progress; they include three new wards and additional accommodation for the nursing staff. The new wards are being given (£30,000) by Mr. and Mrs. G. Foster Clark.

Arsenic in Sweets.

About 30 children have been taken ill in Staffordshire and Cheshire after eating sweets made at a small factory at Burslem, Stoke-on-Trent. It is stated that the arsenic was contained in a dusting powder used to prevent the sweets from adhering to each other. As much as two-thirds of a grain has been found in a single sweet, but as yet there have been no fatal cases of poisoning. Efforts are being made to trace all the supplies distributed to retailers, and 50 bottles have been confiscated. It is believed that several hundredweight of the sweets have been sent out to shopkeepers in an area stretching from Crewe to Leek, including Congleton, Burslem, and Newcastle (Staffs.) The factory has been closed, and parents have been warned to send for medical aid if a child shows signs of illness after eating boiled sweets.

Vacancies

For further information refer to the advertisement columns.

Ascot, Heatherwood Hospital.—Res. Asst. M.O. £300.
Barnsley Beckett Hospital and Dispensary.—Jun. H.S. £140.
Barnstaple, North Devon Infirmary.—Res. M.O. At rate of £150.
Bath, Royal United Hospital.—Asst. H.S. At rate of £120.
Bedford County Hospital.—H.S. £175. Also Asst. H.S. £130.
Birmingham, Ear and Throat Hospital, Edmund-street.—Res. Anæsthetist. At rate of £150.
Birmingham, Selly Oak Hospital.—Cas. O. £200.
Blackburn Royal Infirmary.—4th H.S. £150.
Bradford City.—H.P. for Grassington Sanatorium. £225. Locum Assistant Pathologist. £12 12*s.* weekly. Vacancies on Staff of City Pathologist and Bacteriologist. £600.
Brighton, Royal Alexandra Hospital for Sick Children.—H.S. £100.
Brighton, Royal Sussex County Hospital.—Cas. H.S. £120.
Bury Infirmary, Lancashire.—Third H.S. At rate of £150.
Cambridge, Addenbrooke's Hospital.—H.S. Also H.S. to Special Depts. Each at rate of £130.
Cardiff City Council, P.H. Dept.—Half-time Pupil Asst. M.O. £250.
Cardiff, King Edward VII. Welsh National Memorial Association. Area Asst. Tuberculosis Phys. £600. Also half-time Asst. Tuberculosis Officer for Pontypridd area. £300.
Chesterfield and North Derbyshire Royal Hospital.—H.S. At rate of £100–£175.
Colchester, Essex County Hospital.—Asst. H.S. and Reg. £120.
Colchester, Royal Eastern Counties Institution for the Mentally Defective.—Research Worker. £750.
Connaught Hospital, Orford-road, E.—H.P. At rate of £100.
Dartford, Kent, City of London Mental Hospital.—Jun. M.O. £400.
Derby, Derbyshire Hospital for Sick Children.—Res. M.O. At rate of £150.
Dorchester, Dorset Mental Hospital.—Jun. Asst. M.O. £350.
Dublin, Richmond, Whitworth and Hardwicke Hospitals.—Hon. Phys.
East Ham Memorial Hospital, Shrewsbury-road, E.—Res. M.O. At rate of £200. H.P. At rate of £150. H.S. At rate of £120.
Essex, Administrative County of.—Asst. County M.O.H. £500–£700.
Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—Second H.S. At rate of £120.
Great Yarmouth General Hospital.—Sen. and Jun. H.S.'s. £150 and £140 respectively.
Grimsby and District Hospital.—Res. M.O. £200.
Guildford, Royal Surrey County Hospital.—H.S. £150.
Hertford County Hospital.—Res. Surg. O. At rate of £250.
Hôpital Français, 172, Shaftesbury-avenue, W.C.—Jun. Res. M.O. £100.
Hospital for Sick Children, Great Ormond-street, W.C.—H.S., and H.P. Each at rate of £100.
Hospital for Women, Soho-square, W.—Res. M.O. At rate of £100.
Ilford, King George Hospital.—Asst. Res. M.O. £250. Also House Officer. £100.
Infants Hospital, Vincent-square, Westminster.—Two H.P.'s. Each at rate of £75.
Inverness District Mental Hospital.—Jun. Asst. M.O. £350.
Inverness Northern Infirmary.—3rd. Res. M.O. At rate of £100
Ipswich, East Suffolk and Ipswich Hospital.—Cas. O. £150 Also H.S. At rate of £120.
Islington Dispensary, 303, Upper-street, N.—Asst. Res. M.O. £250
Kingston-upon-Hull, City and County of, Beverley-road Institution.—Asst. M.O. £300.
Lanark, County of.—Bacteriologist and Pathologist. £750.
Lancashire County Council.—Asst. County M.O. £800.
Lancaster County Mental Hospital.—Asst. M.O. £350.
Liverpool and District Hospital for Diseases of the Heart.—H.P. At rate of £52.
Liverpool Open-Air Hospital for Children, Leasowe.—Jun. Res. M.O. £200.
London Lock Hospital, 91, Dean-street, W.—Two H.S.'s. Each at rate of £200.
Macclesfield General Infirmary.—Res. H.S. At rate of £180.
Manchester, Ancoats Hospital.—H.S. At rate of £100.
Manchester City Education Committee.—Asst. School M.O. £600
Manchester Royal Infirmary.—Jun. Asst. M.O. for Radiologic Dept. £400.
Manchester Victoria Memorial Jewish Hospital, Cheetham.—Sen. H.S. £250.
Merthyr General Hospital.—Res. H.S. At rate of £150.
Miller General Hospital, Greenwich-road, S.E.—Cas. O. At rat of £150. Also H.P., and H.S. Each at rate of £125.
Narborough, near Leicester, Leicestershire and Rutland Mental Hospital.—Locum Tenens. M.O. 7 gns. a week.
National Hospital, Queen-square, W.C.—Res. M.O. £200.
Newcastle-on-Tyne, Royal Victoria Infirmary.—Hon. Surgeo to Throat and Ear Dept.
Newcastle-upon-Tyne, Hospital for Sick Children.—Jun. H.S At rate of £100. Also Res. H.P. and Res. Sen. H.S. Eac at rate of £95.
New Zealand, Christchurch Hospital Board.—Med. Reg. £50
Northampton General Hospital.—H.P., Two H.S.'s, and Tw Asst. H.S.'s. Each at rate of £150.
Northwood, Middlesex, Mount Vernon Hospital.—H.S. £200.
Nottingham Children's Hospital.—Res. H.S. At rate of £150.
Nottingham General Hospital.—Cas. O. Also H.P. Each at rat of £150.
Oldham Royal Infirmary.—Two H.S.'s. Each at rate of £17
Plymouth, City Hospital.—Res. M.O. £350.
Pontypridd Women's Welfare Centre.—Woman Doctor for Birt Control Clinic. 1½ gns. per session.
Poole, Dorset, Cornelia and East Dorset Hospital.—H.S. A rate of £150.
Portsmouth Royal Hospital.—Sen. H.S. At rate of £175. Als H.P., Two H.S.'s, and Cas. O. At rate of £130 and £10 respectively.
Preston and County of Lancaster Royal Infirmary.—H.S. A rate of £150.
Princess Louise Kensington Hospital for Children, St. Quintin avenue, N. Kensington, W.—H.S. and Cas. O. At rat of £75. Also Hon. Physician and Hon. Radiologist.
Reading, Royal Berkshire Hospital.—Cas. O., and Res. Anæsthetist. At rate of £150.
Royal Free Hospital, Gray's Inn-road, W.C.—Asst. Physicia
Royal Waterloo Hospital for Children and Women, Waterlo road, S.E.—Hon. Clin. Asst.
St. Bartholomew's Hospital, E.C.—Asst. Surgeon for Diseases Throat and Nose. Asst. Surgeon to Orthopædic Dept. Als Asst. Dental Surgeon.
St. Helen's Hospital.—H.S. £250.
Salford Royal Hospital.—H.S. to Orthopædic Dept. Also H. Each at rate of £125.
Salop County Council.—Asst. M.O. £600.
Sheffield Royal Hospital.—Res. H.S. Res. Anæsthetist. Tw H.S.'s. Also Ophth. H.S. All at rate of £80.
Shrewsbury, Eye, Ear, and Throat Hospital for Shropshire.—H. £200.
Southampton, Royal South Hants and Southampton Hospital.—Asst. H.S. At rate of £180.
South Shields, Ingham Infirmary.—Jun. H.S. £150.
Stafford, Staffordshire General Infirmary.—H.S., and H.P. A rate of £200 and £150 respectively.
Stockport Infirmary.—Res. Surg. O. £250. Also H.P. £175.
Swansea Hospital.—H.S. £150.
Talgarth, Breconshire, Mid-Wales Counties Mental Hospital.—Asst. M.O. £350.
Taunton and Somerset Hospital.—Sen. H.S. At rate of £150.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—H. At rate of £100.
Walsall General Hospital.—H.S. At rate of £150.
Walsall, Manor Hospital.—Res. Asst. M.O. £200.
Warrington, Whitecross Hospital.—Asst. Res. M.O. £225.
West Lothian, Bangour Mental Hospital. — Second Ass M.O. £350.
Wigan County Borough Education Committee.—Asst. Scho M.O. £500.
Wolverhampton and Midland Counties Eye Infirmary.—H. £150.
Woolwich and District War Memorial Hospital, Shooters Hil S.E.—H.S. At rate of £100.
Worcester, Besford Court Catholic Mental Welfare Hospital f Children.—Res. Med. Reg. At rate of £150.

The Chief Inspector of Factories announces vacant appointmen for Certifying Factory Surgeons at Littlehampton (Sussex Flint (Flintshire), and Glenluce (Wigtownshire).

The Home Secretary gives notice that in consequence of th resignation of Dr. David Duke Monro, Medical Refere under the Workmen's Compensation Act, for Wigtow County (Sheriffdom of Dumfries and Galloway), the appoin ment held by him is vacant. Applications for the po should be addressed to the Private Secretary, Scottish Offic Whitehall, London, S.W.1, and should reach him not late than Sept. 27th.

NOTES, COMMENTS, AND ABSTRACTS

AN EXPERIMENTAL WORKSHOP COLONY FOR TUBERCULOSIS AT BRESLAU.

THE colony established by the Society for the Control of Tuberculosis at Breslau in the grounds of the Municipal Tuberculosis Hospital of Breslau-Herrnprotsch has now been running for a year. It was opened on July 1st, 1929. Out of 32 houses intended for the use of one family, 30 had been let by May 1st, 1930, and in the two homes for unmarried persons, 27 of the 35 beds had been taken by women; 8 single men are living as sub-tenants in the family houses, and applications have been made for the remaining accommodation, so that the colony is almost full.

THE PROBLEM.

The workshop colony is an attempt to solve the housing problem for persons who are unsound, or incapable of complete recovery, by offering them treatment for an indefinite period under conditions which are favourable to work, and which at the same time leave the invalid in the care of his family. The arguments urged against dwelling-colonies for tuberculous patients do not affect workshop colonies, which should be regarded as a necessary complement of the tuberculosis hospital; the introduction of work therapy should be contemplated from the beginning in planning future hospitals. The conception of a combination of a hospital and a workshop colony was first put into practice at Papworth, where institutional treatment is given to those persons who need it for a limited period, while treatment of long duration is carried out by the domestic and medical provisions of the work-shop colony.

The Breslau Society for the Control of Tuberculosis undertook the scheme in 1927 at the instigation of Dr. Ernest Brieger, who had studied the Papworth plan closely, and is now more firmly convinced than ever that a work-shop colony can only be developed with success in connexion with an institution, and under the direction of the physician in charge.

The plan followed by which houses of four to five rooms intended for the use of one family only were built, has the advantage that the affected person can live in the upper story almost completely isolated from the family. For families without children the houses are somewhat expensive, and in future a certain number of smaller and simpler houses will be built. Arrangements have been made to allow the heating for the small houses to be introduced from the two homes for unmarried persons. In each house a small kitchen is supplied which is not intended or constructed as a living room, and food is cooked by gas, an average gas bill reaching from 8 to 15 marks per head. The invalid's room is let suitably furnished, and under the hire-contract no further furniture may be installed. The same principle holds in the homes for unmarried persons, each of whom occupies a room to herself, with running water laid on.

FINANCE.

The cost of the whole project, including inside fittings, was between one and two million marks, of which 160,000 were lent by the Imperial Insurance Institution at 6 per cent., 150,000 by the General Local Sick Fund of Breslau, at 7 per cent., and 300,000 by the National Insurance Institution of Silesia, at 6 per cent.; 25,000 marks were placed at the disposal of the Society by the Imperial Ministry of Labour, and 2000 marks each by the German Central Committee and the Ministry of Welfare, respectively. The interest on this capital could clearly not be raised from the tenants themselves. The rent has been fixed at 115 marks per month, a figure which it will be possible to maintain as long as an annual subsidy of 7000 marks is received from the tax on house-rent. Rent of a furnished room is 100 marks, but such sums cannot be borne by the tenants alone; the National Insurance Institution has granted 2·50 marks per day for married or single patients. The remaining 40 marks per month are raised by the tenant and, in the case of married recipients of benefit, the town of Breslau plays a part; in the case of unmarried persons the Welfare Bureau makes a contribution. Most of the patients have passed through the hospital either for examination and observation or for prolonged periods of treatment; they are selected by a committee, and persons belonging to other localities have been excluded from the first. Progressive and hopeless cases were also rejected, and preference given to patients in whom a clinical cure might be expected following protracted treatment under favourable conditions.

THE WORK.

The work offered has been suited to the capabilities and tastes of the workers; tailoring, locksmith's work and joinery are some of the trades in which patients are employed. The directress of the sewing-room was a patient for three years and has designed a new form of invalid attire; the whole of the necessary linen of the Herrnprotsch Institution is now being produced in the workrooms, which are equipped with electric sewing and knitting machines. Patients work two to four hours daily, and their wages amount from 20 to 50 marks a month. Joinery is carried on as a self-supporting trade, and coffins are produced for the municipal infirmaries at the rate of about 40 a month. In the locksmiths' workshop, steel house fittings are manufactured, and will bring in a living wage as long as sufficient work can be found. The bookbinding section is beginning to make headway, although it is still unremunerative.

The effects of the scheme, almost throughout, have been an improvement in the weight, depression and clinical and X ray findings of the patients, who are with difficulty restrained from doing more than the prescribed amount of work. The difficulty of maintaining the supply of employment is still a serious one, and a work period of more than four hours at a time cannot be guaranteed. Although it is too early to judge of the ultimate success of the colony, the initial success cannot be denied. It is creditable to have ensured a suitable way of life for 80 cases of recognised tuberculosis, but it is even more satisfactory to have provided a healthy environment for 60 children coming of tuberculous parentage. Careful supervision is exercised, and the children are all radiographed and examined at intervals; a school and kindergarten are in the process of erection.

THE FUTURE.

Without energetic help from all classes of the community, constructive work is impossible in these days of economic need. Without assistance the work from the National Insurance Institution shops could not have been developed, and even yet they are housed in unsuitable quarters. There is reason to hope, however, that the German Central Committee will offer such support as will make the construction of modern work-shops possible. Dr. Brieger, who is in charge of the hospital and colony, is cautious in his estimate of the value of the scheme.[1] It is easy, he says, to start. The difficulties will only become fully apparent when the new principle has been carried out in its entirety.

FOOT-AND-MOUTH DISEASE.—The Ministry of Agriculture announces that foot-and-mouth disease has appeared at Holbeck, Leeds. This is the first outbreak in Great Britain this year.

PATHOLOGICAL AND BACTERIOLOGICAL LABORATORY ASSISTANTS' ASSOCIATION.

TRIENNIAL CONFERENCE.

THE third triennial conference was held in the medical school of the University of Manchester from August 25th to 29th. The conference was opened on August 25th by Dr. W. H. Lang, D.Sc., F.R.S., Prof-Vice-Chancellor and Barker Professor of Cryptogamic Botany in the University. He emphasised the value of the skilled assistance and coöperation of laboratory assistants in any research work and congratulated the association on its efforts to raise the status and improve the training of technical assistants. The vice-president, Mr. C. W. Ashton, then welcomedthe members to Manchester. The mornings of the conference were devoted to various lectures and papers delivered in the lecture theatre of the Medical School, and an exhibition of laboratory work and apparatus was displayed. On Wednesday, August 27th, the conference visited Liverpool where Prof. W. Blair Bell gave a lecture on Laboratory Research in Cancer.

The conference dinner was held on August 28th. The principal guests were the Pro-Vice-Chancellor, Prof. A. E. Boycott, F.R.S., Dr. D. Stewart, Dr. W. Susman, and Dr. A. F. C. Davey. During the evening the Sims Woodhead Memorial Medals were presented to Prof. Boycott and Mr. W. A. Mitchell (Cambridge) for conspicuous service to the Association. Mr. A. Norman and Mr. J. McLean spoke of work done for the Association by the recipients, especially in the earlier days of the Association, when it was fundamental to the success of the movement that the sympathy of the laboratory chiefs should be obtained.

Prof. Boycott said that his position as Secretary of the Pathological Society of Great Britain and Ireland at the time the Association was formed had allowed him to dispel the fears of that Society that it was designed to usurp the Society's activities. The attendance at the conference showed how widespread is the organisation of the Association, members attending from Uganda, North and West Ireland, as well as from all parts of England and Scotland.

PSYCHOLOGY OF THE SMALL CHILD.

MOST of the problems in the life of children in the early school years are helpfully discussed in a small book [1] recently published which deserves attention. The volume is ambitious in scope. For example, the imaginal, intellectual, and creative life of children at the fifth year are subjected to long consideration, and even such difficult problems as the child's spiritual needs are discussed. Despite the scientific difficulties of this last topic, the authors have achieved some measure of success in this section. Various activities of the older child are then dealt with—physical, social, constructing, literary—and on each subject sound sense is offered in attractive language. The chapter on types of children is not quite so happy. Understanding of the maladjusted child cannot be obtained satisfactorily in the absence of an understanding of the unconscious operations of the mind. The authors should make a separate volume of this chapter.

[1] The Child from Five to Ten. By Evelyn and Miriam Kenwrick. London: Kegan Paul, Trench, Trübner and Co., Ltd. 1930. Pp. 299. 7*s*. 6*d*.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL.—The annual report once more brings out the difference in the death-rate between "booked" and "emergency" cases. There were last year 2360 in-patients—1916 married women and 444 single women with their first child. The death-rate for "booked" cases was 3·2, and for "emergency" cases 43 per 1000; the infantile death-rate in the former category was only 25 per 1000 as compared with 153 in the latter. The number of women attended in their own homes was 1546, and for the third year in succession there were no maternal deaths. The first patients were received into the new isolation block at Hammersmith last week.

Medical Diary

LECTURES, ADDRESSES, DEMONSTRATIONS, &c

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Sept. 15th, to SATURDAY, Sept. 20th.—WESTMINSTER HOSPITAL, S.W. Post-graduate Course in Medicine, Surgery, and the Special Departments occupying each day from 10.30 A.M. to 5.30 P.M., with lectures and demonstrations. Men only. Fee £5 5*s*. Copies of syllabuses for forthcoming courses may be obtained from the Fellowship of Medicine, 1 Wimpole-street, W.1.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Sept. 15th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose and Throat Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M. Medical, Surgical, Throat, and Ear Clinics. Operations.

FRIDAY.—10.30 A.M.: Ear, Nose, and Throat Clinics. 2.30 to 5 P.M.: Medical, Surgical, and Children's Diseases Clinics. Operations.

Appointments

ADAMS, J. R., M.B. Edin., D.P.H., has been appointed County Medical Officer for Roxburgh.

BACH, FRANCIS, D.M. Oxf., Medical Registrar to the British Red Cross Society's Clinic for Rheumatism, Peto-place, London.

BROWNLIE, J. L., M.D. Glasg., D.P.H., a Medical Officer of the Department of Health for Scotland.

GREGORY, J. C., M.R.C.S., L.R.C.P., House Physician to Medical Unit, University College Hospital, London.

JACK, James, *M.C.*, M.B. Glasg., Medical Officer of Health for the city of Durham.

SHARP, C. J. H., to be Certifying Surgeon under the Factory and Workshop Acts for the Linslade District of the County of Buckingham.

STEPHENSON, H. M., to be Certifying Surgeon under the Factory and Workshop Acts for the Maiden Newton District of the County of Dorset.

TOPPING, ANDREW, M.D. Aberd., D.P.H., Medical Officer of Health for Rochdale.

Births, Marriages, and Deaths

BIRTHS.

CHAMBERS.—On Sept. 6th, in London, the wife of Guy Chambers, F.R.C.S. Eng., of Ryde, and Bolton-gardens, S.W., of a son.

COLE.—On Sept. 5th, at Trumpington-street, Cambridge, the wife of Leslie Barrett Cole, M.D. Camb., M.R.C.P. Lond., of a son.

DANBY.—On Sept. 7th, 1930, to Victoria (née Arkell), wife of Alfred Danby, F.R.C.S.E., at the Homestead, Woodbourne road, Birmingham—a daughter.

GLADSTONE.—On Sept. 5th, at The Old House, Rendcomb, Cirencester, the wife of F. C. Gladstone, D.M. Oxf., of a son.

KEYS.—On Sept. 1st, at Ravello, Ruislip, the wife of Sidney Hudson Keys, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

MILLER.—On Sept. 1st, at Grosvenor-road, Tunbridge Wells, the wife of T. Mackinlay Miller, M.R.C.S., L.R.C.P. Lond., of a son.

MONCRIEFF.—On Sept. 2nd, Honor (née Wedmore), wife of Alan Moncrieff, M.D., M.R.C.P., of a son.

MARRIAGES.

BASSETT—BURRELL.—On Sept. 3rd, at St. Paul's Church, Edinburgh, John Mories Bassett, M.D., F.R.C.S. Edin., only son of W. Bassett, Christchurch, New Zealand, to Kathleen Alicia, eldest daughter of the late H. M. Burrell, Edinburgh.

PEEL—MONYPENY.—On Sept. 2nd, at Fisherwick, Presbyterian Church, Belfast, Albert A. Fitzgerald Peel, M.A., D.M. Oxf., son of Dr. A. A. Peel of Glasgow, and Crumlin, Co. Antrim, to Mary Watson Monypeny, M.Sc., daughter of the late Dr. William Monypeny of Belfast.

DEATHS.

MARK.—On Sept. 5th, at Oxford-terrace, W., after a long illness, Leonard Portal Mark, M.D., son of the late Edward W. Mark, late Consul of Marseilles.

MUSGRAVE.—On Sept. 2nd, Cecil B. T. Musgrave, M.D. Lond., M.R.C.S. Eng., L.R.C.P. Lond., of Domain, Mullion, Cornwall, last surviving son of the late Colonel Musgrave, 5th Bengal Cavalry.

WALLACE.—On Sept. 5th, at Howard Lodge, Newport-road, Cardiff, Thomas Wallace, M.D.R.U.I., J.P.

WARREN.—On Sept. 2nd, following an operation, Alfred Castle Warren, M.D. Camb., L.R.C.P. Lond.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ADDRESSES AND ORIGINAL ARTICLES

THERMAL ADJUSTMENT OF MAN AND ANIMALS TO EXTERNAL CONDITIONS.*

By Sir Charles J. Martin, C.M.G., M.B., D.Sc., F.R.C.P. Lond., F.R.S.,

RECTOR OF THE LISTER INSTITUTE OF PREVENTIVE MEDICINE; PROFESSOR OF EXPERIMENTAL PATHOLOGY IN THE UNIVERSITY OF LONDON.

LECTURE II.

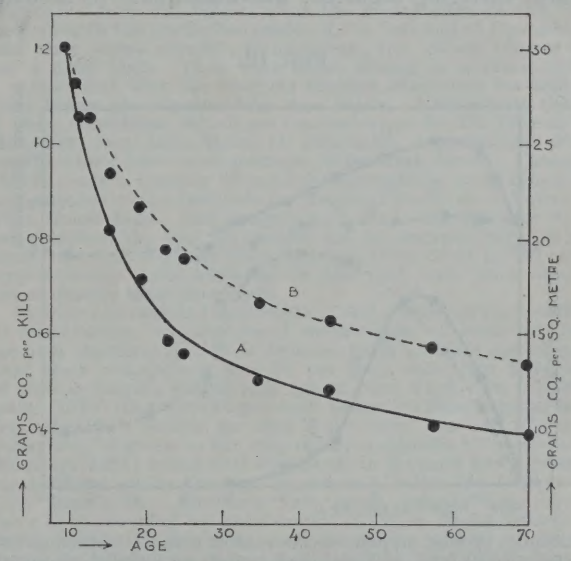
CHEMICAL synthesis on a large scale is confined to ants. It is reductive in character, the requisite ergy coming from sunlight. In animals, on the whole, e reverse oxidations occur, most of the energy nning down to heat. In all living cells this slow idation of foodstuffs takes place under the influence catalysts at a comparatively low temperature. terposed in this chain of irreversible oxidations e reversible chemical mechanisms which catch d store some of this slow downward flow of energy, e most notable and best-studied being muscle. muscle cell is like an accumulator on an electric rcuit in which the electrical energy is otherwise nning away to heat. It stores some portion of it d this portion can subsequently be suddenly let ose to do work. By appropriate arrangements a oportion of this work can be utilised outside the ll but most of it is lost, and the maximum efficiency the most practised muscular act is only about per cent.

Regulation of Temperature by Varying roduction: The Source of Animal Heat.

Of recent years cellular oxidations have been much udied outside the body, notably by Batelli and ern, Harden and Maclean, Thunberg, Warburg, els and Grafe.† That the auto-oxidations occurring an emulsion of tissues in a pot are always the me as occur in the body is, however, unlikely. parated from the body, the cells of all the different gans and from all sorts of animals, use weight for ight very much the same amount of oxygen at the me temperature, whereas in their normal circum- nces their rate of combustion is quite different d, generally speaking, much less. Isolated, auto- idation seems to run riot, normally to be controlled. is held by Grafe that this control, which he calls 'damper action," is brought about in some obscure y by means of the sympathetic nervous system. The rate at which oxidation takes place in resting ls with their circulation intact has been extensively udied by the experimental procedures introduced by rcroft and Brodie (1906), and for our knowledge on e subject we are indebted to them and their many ciples. The method depends upon the determination the oxygen in the blood entering and leaving the rticular organ and the rate of the circulation. e principal results are collected by Loewy (1925) his article on the metabolism of individual organs. Different tissues vary a good deal in the rate at hich they use oxygen. Of all the tissues examined, ting muscle uses least and kidney most, weight for ight. The results of different observations vary considerably, but may be summarised by saying that the heat production of a kilogramme of resting muscle is about one large calorie per hour, of liver, pancreas and submaxillary gland, about eight and of kidney 25 kilocalories. Although this has not been satisfactorily established for isolated tissues, the oxygen utilisation of the whole body varies much with age. This is well illustrated by Fig. 9 which is a graph drawn from observations by Sondén and Tigerstedt (1895).

Six to twelve persons of age groups ranging from seven to seventy were enclosed in a large respiration chamber of 3,370 cubic feet capacity for two hours, and the carbon dioxide produced was determined each half hour. The temperature of the chamber was 18 to 20° C. and the individuals were resting. As may be seen from the lower curve of the chart, the combustion rate at seven years of age is, weight for weight of body, twice that at 25 and three times that at 70 years of age. The upper curve shows the same relation reckoned on the basis of body surface. It will be obvious why, apart from their greater activity, children want so much to eat!

FIG. 9.



Influence of age on combustion-rate of man. Upper graph, grammes CO_2 per sq. metre body surface; lower graph, per kilo body-weight, according to age-grouping. From observations by Sonden and Tigerstedt (1895).

The resting gaseous metabolism is also increased by the intake of food. The warming effect of a good meal is familiar to all. This is not due to the extra work performed by the alimentary canal, for plenty of work can be supplied for the stomach and intestines to do by filling the stomach with agar, but this does not appreciably increase the utilisation of oxygen It is a specific effect of food and the explanation for it is still far from clear. The three varieties of food are effective, but with proteins the increased combustion is greater and lasts longer. Fig. 10 illustrates this well-established fact. It is from an experiment by one of my pupils who is an unusually good subject for observations on metabolism. In her case, 600–700 calories in the form of either carbohydrate or protein produced about 30 per cent. rise in the rate of oxygen consumption. With the carbohydrate, the rise occurred more rapidly but lasted less than half the time, so that the total effect is about a third.

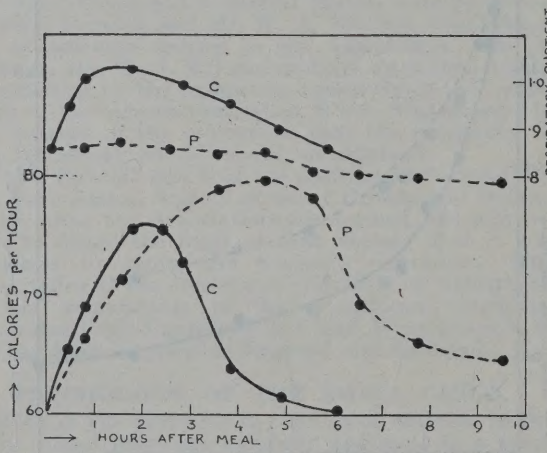
* The Croonian Lectures delivered before the Royal College of ysicians of London on June 12th, 17th, and 19th. Lecture I. s published in THE LANCET last week.

† The literature is reviewed by Grafe, Biochem. Zeitschr., , 102.

EVIDENCE FOR CHEMICAL REGULATION IN MAN.

Lavoisier (1778), who, by his discovery of oxygen explained the nature of combustion, also proved that oxidation was the source of animal heat, and showed that a cooled man used more oxygen than a warm one. One hundred years later, Voit (1878) studied the effect of external temperature on the rate of combustion of man and found that with a clothed man in still air the external temperature could be varied from 10–25° C. without appreciable change in the amount of carbon dioxide he produced, but as soon as the rate of heat loss increased beyond this, he began to burn more fuel and ultimately to shiver. Speck (1883, 1885) measured the carbon dioxide he produced whilst sitting in a cold bath, but as long as he was able to keep absolutely still he found no significant rise. Rubner (1900) who obtained results very similar to those of Voit was of opinion that the amount of muscular movement, until shivering occurred, was inadequate to account

FIG. 10.



Influence of food on combustion-rate of man. C = effect of 700 calories in form of starch and lactose on metabolism (lower curve) and respiratory quotient (upper curve). P = effect of 650 calories in form of raw steak. Observations by Mrs. Y. M. Gibbs. Weight, 59·2 kilos; height, 177 cm.; age 24. After fasting 14 hours.

for the increased combustion observed and concluded that the extra combustion took place in muscles without motion and in other organs, especially the liver.

In 1890 Loewy (1890) measured the oxygen used over a short period by a number of people before and after removing their clothes and concluded that in all cases in which an intelligent person was completely relaxed, the utilisation of oxygen was no greater, unless they shivered, when it might increase 50–100 per cent. Various criticisms were levelled against this conclusion and six years later Johansson (1896) performed a number of experiments on himself and another, with and without clothes, in a chamber at 15–20°. The experiments lasted one to two hours. Johansson arrived at the same conclusion at Loewy—viz., that unless shivering occurred, there was no increased formation of carbon dioxide; coincident with shivering the carbon dioxide output rose 70–80 per cent. and even to three times its former value. Johansson's results were criticised by Rubner, but not upset, and physiologists settled down for 25 years to the general belief that, unlike animals, man relied upon physical regulation until the fall in temperature of his skin was sufficient to evoke shivering.

In 1914 Leonard Hill recorded some experiments and Flack had made on the respiratory exchange eight individuals, firstly, in the laboratory, and th on the roof of the London Hospital, with a co breeze blowing but at a temperature not cold enou to cause shivering. From Hill's data, I find that t mean oxygen consumption outdoors was 1·4 tim what it was indoors. These observations we published in the Reports of the Local Governme Board and escaped the attention they deserved unt in 1921 Campbell, Hargood-Ash and Hill repeat them, with similar results, and discussed th significance in a paper in the *Journal of Physiolo*. Hill's experiments have been criticised on the groun that the subjects were neither at complete rest n fasting. This, however, applies to the experiments comfortable surroundings as well as when expose. I have no doubt of the substantial accuracy of Hil conclusions, though the increases in metabolism obtained are perhaps somewhat high. I have fou a rise in oxygen consumption in most subjects soon as the surface of the body became uncomfortab cold. We both used the Douglas-Haldane metho but in my experiments the subjects were in the po absorption state and had been at complete rest f some hours, generally all night.

The oxygen consumption in a warm bed was first taken a standard of reference. Then the clothes were removed a windows opened and a cool winter's breeze (temperatu 8–10° C.) allowed to play upon the nearly naked body. T rate of cooling was, therefore, greater than in Hill's cloth subjects. After half an hour's interval, during which t skin temperature of the thighs fell to 25–26° C. and "goo flesh" appeared on the limbs, the respiratory exchan was again measured. Four individuals were the subjects the experiments, two thin and two well covered. The increa in metabolism varied from 9 to 17 per cent. It was m in the thin persons. On two occasions the experiment w extended until shivering seemed imminent, as there was tremor on the respiratory rhythm and slight flickering some muscle bundles. In these cases the increase amount to 26 and 30 per cent. respectively.

Similar observations have been made by Franke a Gessler (1925). They determined the effect of removi their clothes in a room of which the temperature was 15°. They found their oxygen combustion increased 12 to 24 p cent. on different occasions although they did not exp themselves sufficiently long to shiver.

Gessler and Laves (1925) made the further interesti observation that 0·3 g. of pyramidon or 30 c.cm. of alcol obliterated this chemical response after removing cloth

When Franke and Gessler placed their legs in cold wat a 10 per cent. rise was noticed, but when they did the sa to a patient with anæsthesia from a transverse myeli there was no rise in metabolic rate and the body temperatu fell 0·5° C. From this they conclude that cold to the sk is a more effective stimulus to chemical regulation than a f in temperature.

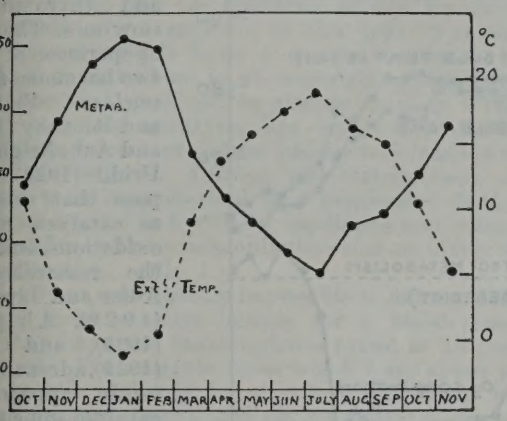
Liljestrand and Magnus (1922) made some interesti experiments which are generally taken as supporti Johansson. They immersed themselves in baths at 32° containing carbon dioxide super-saturated water at Moritz. The carbon dioxide prevented the normal constr tion of the skin vessels, in fact, dilated the capillaries a abolished the uncomfortable cold feeling, although the bo temperature sometimes fell 1° C. Nevertheless, they fou that they did not shiver nor did their oxygen consumpti increase unless the temperature of the bath were lowered 29° C. These experiments do not seem to me to be nec sarily in favour of Johansson's rigid conclusion, but indicate that the stimulus to enhanced combustion is mo readily produced by a cold skin than a drop of 1° C. in blo temperature.

How, then, are we to explain the inconsistenci between the experiments of the Swedish school a others. Gessler suggests that Johansson must ha hypnotised himself and his companion, for Gessl and Hansen (1927) have shown that suggestion ca inhibit contraction of the vessels to the skin a shivering, even though the body temperature fal from the consequent heat loss. I have no dou that the real explanation for these divergent vie

that different individuals vary in the readiness with hich they respond by chemical regulation and that e discrepancies are especially likely to be encountered hen the experiments are of short duration. Pre-mably the larger the number of people experimented on the more will this become apparent. Gessler, ho has had in his clinic more experience than can claim, emphasises that whilst the same person sponds in a remarkably consistent way, he experiences eat differences between individuals.

An interesting fact first brought to light by the servation of Hill and his colleagues (1922) is that tients undergoing open-air treatment not only

FIG. 11.



Mean monthly metabolism and mean monthly temperature. Gessler (1925), observations on himself.

hibit very considerable increase in the respiratory change at rest over that occurring when they are pt indoors at 70° F., but that the effect persists for ne time. Just as the effect of a cold bath is obvious e hour afterwards, so the effect of a month's exposure nifests itself, so I am informed by Hill and Campbell, about a fortnight after a child is brought indoors. this is the case, a seasonal influence upon basal tabolism should be discoverable. Benedict (1915), o denies chemical regulation without shivering, orts casually that one of his trained subjects had an per cent. higher respiratory exchange in winter than summer, but an experiment by Gessler is more minating. He observed his oxygen consumption the same hour every third day throughout the year er reclining for half an hour. The results of this ended experiment are to be seen in the graph g. 11) in which the mean monthly basal metabolism l the mean monthly air temperature are plotted ainst months of the year. His day to day variations metabolism amounted to only 3 per cent. It will seen from the graph that the mean oxygen con-nption at rest varies inversely with the mean external perature and is 10 per cent. higher in January n in July, notwithstanding an increase of 10 lb. weight during the summer.

So far we have been considering more particularly effect of a cold skin in raising combustion rate. will now examine whether the reverse occurs l in warm climates basal metabolism is diminished. is would seem advantageous, and the earlier ervations on the effect of external temperature on respiratory exchange of man by Rubner and his istant, Wolpert (1898), indicated that it occurred. servation of a possible depressing effect of a warm n upon metabolic rate is easily obscured by an rease in oxygen consumption should the body temperature rise. Plant and Wilbrand (1922) got over this difficulty in an ingenious way and found that when a man or dog was made hyperthermic and then allowed to cool down until his temperature was again normal, the man's basal metabolism was reduced 8 per cent. and the dog's about 30 per cent. They conclude that this "gegenregulation" was in operation during the hyperthermic period but was masked by the direct effect of rise in temperature on cell combustion.

Basal Metabolism in the Tropics.

If the continued absence of the stimulus of cold upon the skin leads to a depression of gaseous metabolism below that found in what we are accustomed to regard as comfortable surroundings, it should be manifest in Europeans living in tropical countries.

Eijkman (1896) was the first to measure the respiratory exchange of Europeans in the tropics (Java), and came to the conclusion that it did not differ significantly from that of persons of similar size, age and weight in Berlin. I have calculated from his figures what the metabolism should be according to the prediction tables of Du Bois and of Benedict, and they agree closely; if anything, the values observed are a little high. They were taken sitting in a chair, and I cannot find that the subjects reposed absolutely for some time before the observations were made. I anticipate that if these conditions, which are insisted upon by Du Bois and Benedict, had been those of Eijkman's experiments, his results would have been perhaps 10 per cent. lower. Young (1919) made a number of careful observations upon himself and another at the Institute for Tropical Medicine in Townsville, Queensland. The analytic part of the experiments was unexceptionable, but his results are so unexpectedly high that I can only suppose the subjects of them must have been hyperthermic, even allowing for the fact that they were taken shortly after breakfast.

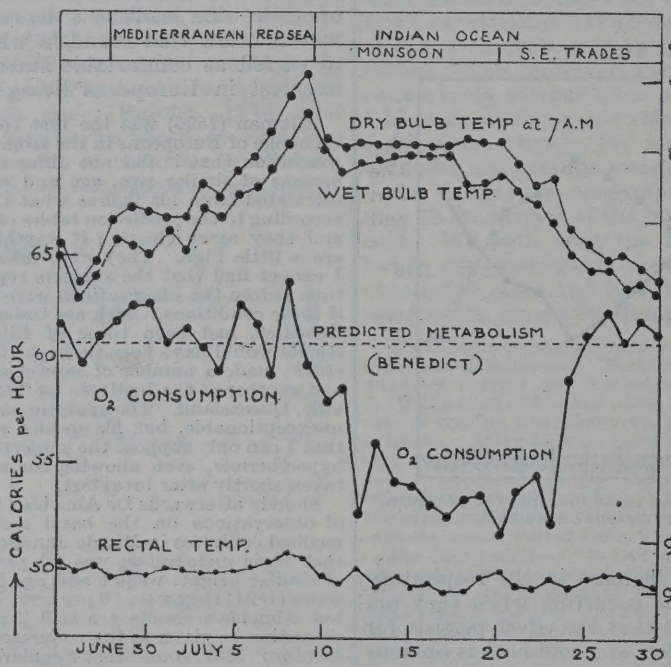
Shortly afterwards De Almeida (1921) published the results of observations on the basal metabolism of some of his medical confrères in Rio de Janeiro, from which it appeared that their metabolism was 20 per cent. less than persons of similar height, weight and age in New York. In a later series (1924) they were 16 per cent. below Du Bois' standards. but Almeida's results are still 2 per cent. too low if consideration be given to the respiratory quotients he obtained. Montoro (1921) found that Spaniards in Havana had a basal metabolism, on the average, 14 per cent. below the accepted U.S. standards. Similarly low basal metabolism rates have been recorded by Sundstroem (1926) in North Queensland, and by Hafkesbring and Borgstrom (1926) in New Orleans. Hindmarsh, who examined 76 subjects in Sydney, New South Wales, found an average diminution of 9 per cent. in men and 10 per cent. in women. Lastly, the question has been examined with extraordinary care and thoroughness by Berkhout (1929) in Eijkman's old laboratory at Weltevreden, Java. The mean of his observations on twelve Europeans represents a 10 per cent. diminution in metabolism, which is twelve times the probable error.

When the individual observations of all these different observers are scrutinised, considerable variations are to be found among them. Therein rests, I think, the cause of the divergence of opinion. Individuals react differently: some reasonably reduce their resting rate of combustion in warm climates, others do not.

In 1923 I took advantage of a voyage to Australia, during the time of year when I should experience the hottest weather in the passage through the tropics, to see whether I made any attempt to moderate my combustion rate. A voyage on a liner possesses signal advantages for such an experiment, as one can order one's life with the utmost uniformity. I took the same quantity and quality of food at the same intervals daily, and the same amount of exercise throughout the voyage. At 7 A.M. each morning, before I stirred from my bed or took food or drink, I breathed into a Douglas' bag for 15 minutes. I at once measured the volume of air breathed, removed samples into syringes over mercury, and analysed them during the morning. From the volume of air breathed and the oxygen removed from it and the

carbon dioxide it had gained, the volume of oxygen, at 0° and 760 mm. pressure, used per minute and the respiratory quotient were arrived at. From these data the number of calories produced per minute was calculated from the oxygen consumed and the respiratory quotient (Zuntz and Schumberg (1901)). The results I obtained are shown graphically in Fig. 12, in which the rate of heat formation in calories per hour is plotted for each day. The temperatures of the dry and wet bulb thermometers in °F., observed in the port-hole of my cabin with a good breeze coming through, is recorded above, and the rectal temperature on rising is plotted below. The abscissa represents the 35 days of the voyage. The temperatures recorded usually represent the minimal temperatures endured, for 7 A.M. is nearly the coolest time of the 24 hours in the tropics.

FIG. 12.



Daily observation of basal metabolism of C. J. M. during a voyage from London to Australia, June–July, 1923, and daily record of the temperatures of the dry and wet bulb thermometers at 7 A.M.

I also made daily determinations of the basal metabolism of a medical friend who was a fellow passenger. These observations, too, were made before he arose from bed. He performed his part of the investigation most excellently, but he was an unsuitable subject. I was not able to control his food supply and habits as I was my own, but I do not think that was the explanation of the fact that his consumption of oxygen varied 10–15 per cent. from day to day, and it was not obvious that warm weather had any other effect upon it than to vary it more.

You will notice that within a few days of encountering hot weather my metabolism, on awakening in the morning, began to fall, and that the minimum was not reached until five days after I began to feel the heat. In other words, it was not a quick adjustment. The same happened on encountering the trade winds, but in this case the reverse response was quicker, and accompanied by an urge to activity and a greatly increased output of urine. The maximal difference between the oxygen consumption during the hot and cool periods only amounted to 12 per cent.

We may now consider how an adjustment which persists is likely to be made. If it were an alteration in the rate of combustion in the muscles, liver and other glandular organs, brought about reflexly by stimuli coming from the nerves of temperature sensation, shortly after the particular stimulus ceased the rate might be expected to return to the normal, for the rapidity of the response to the stimulus of cold by increased heat production and its prompt cessation on removal of the cutaneous stimulation was shown by Pembrey (1893). The explanation that seems to me most probable is that we have here an example of the indirect method of varying heat production through the greater or less activity of t adrenals, and particulary the thyroid gland, the i portance of which in thermoregulation is so strong urged by Cramer and by Cannon.

The calorigenic action of adrenalin is rapid, that thyroxin slow, but persistent. According to Au Bright and Uridil (1922), adrenalin produces effect upon oxygen utilisation in minutes which tak days with thyroxin. Plummer and Boothby (192 found the maximal effect of thyroxin occurr ten days after intr venous injection. this account adr nalin would be usef for rapid adjustme and thyroxin f slow ones. The mo of operation of the two hormones is st unclear. Plumm and Boothby (192 and Aub, Bright a Uridil (1922), su pose that they a as catalysts to c oxidations, and fro the researches Adler and Lipschi (1922), Ahlgr (1925), and Eul (1929), adrenalin c tainly appears catalyse some of t auto-oxidation pr cesses in cells moved from t body.

Whilst agreei with Cramer a Cannon that var tion in cell co bustion, due varying activity the adrenals a thyroid, plays a part in thermal adjustment, a believing that an adaptation of the activi of the thyroid gland is the cause of persisti increase or decrease of resting metabolism aft exposure to cold or warmth, I think they incline exaggerate the part ordinarily played by this humo method in thermal adjustment. The experiments Hildebrandt (1921) on rats, Grafe and Redwitz (192 on dogs, and Isenschmid (1922) on cats show that animal some time after thyroidectomy can regula its temperature by varying production of he similarly to a normal one, even when the dorsal co is severed. True, it starts from a lower base lin but failure to compensate is not manifested until t rate of heat loss is considerable. As Isenschmid poin out, the thyroid is not the only instrument at t disposal of the organism for thermal adjustmen it has a whole orchestra to play upon.

GLASGOW LOCK HOSPITAL.—The average stay the 360 in-patients last year was 58·5 days, against 60·2 1928. The average age was 18·1; in the preceding year was 18·5. New dispensary cases numbered 558, a fall of 4 In the in-patient department there were 95 childre 27 fewer than in 1928; 57 of them were infants. I Madeline Archibald, the assistant medical officer, has be appointed whole-time medical officer to see patients who a diffident in going to the clinics at the dispensary, and give regular lectures in the hospital to persons ov 16 years of age, other than students and post-graduates.

CONGENITAL ARTERIOVENOUS FISTULÆ.

By Dean De Witt Lewis, M.D. Illinois,
SURGEON-IN-CHIEF TO THE JOHNS HOPKINS HOSPITAL, BALTIMORE, AND PROFESSOR OF SURGERY IN THE UNIVERSITY SCHOOL OF MEDICINE.

The arterial rankenangioma (racemose or cirsoid erial aneurysm) has been defined as a vascular mour in which all the arteries of a region, including ir finest branches—often communicating with each ier—are dilated and tortuous. Secondarily, the ns, according to most authors, are involved. agner believes that the formation of new vessels is aracteristic of an angioma of this type, that the wly formed vessels have a decided tendency to wth, and that there is an eccentric hypertrophy the vessels of small calibre already existing. The erial racemose aneurysm has been differentiated m lesions known as diffuse phlebarteriectasis and fuse phlebectasis. Diffuse phlebarteriectasis is posed to be characterised by a progressive dilata- n of an arterial bed with its capillaries and veins; ile in diffuse phlebectasis only the veins are involved the dilatation. (Fig. 1.)

Clinically, it is frequently impossible to differentiate ween these vascular lesions, for a blood-vessel on may have the characteristics found in all just ntioned. For example, cases which I am about to ort would probably be classified differently by ferent authors; but as they are congenital in origin, l present the signs and symptoms of a communica- n between the arteries and veins without the ervention of a capillary bed, I believe that they be properly regarded as congenital arteriovenous urysms.

According to Osler, arteriovenous aneurysms strate better than any other disease how borderless the boundaries of medicine and science. The treat- nt of arteriovenous aneurysm, whether congenital traumatic, is essentially surgical, but the shunting arterial blood directly into the veins gives rise certain phenomena which are of interest to the siologist, and produces signs and symptoms ch attract the attention of those practising rnal medicine.

Lewis and Drury state that—

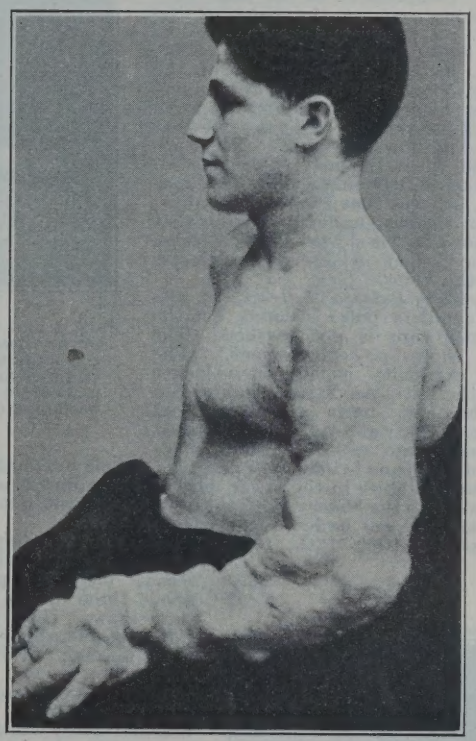
> If blood leaks from the arterial system through channels r than the natural pores provided by capillaries, and s out at a sufficient rate, such leakage will change the rial pressure. So far as many physical signs are concerned eems to be a matter of indifference whether the leak rs back into the ventricle, into the pulmonary artery ugh a patent ductus arteriosus, or into a vein through a ct anastomosis. The leak produces certain changes in rial pressure which are common to all these pathological ditions. That the arterial changes should be identical ll respects in these three separate conditions, however, arcely to be expected, for the leakage in aortic regurgita- is confined to the diastole, while in arteriovenous stomosis and patent ductus arteriosus it occurs through- the whole cardiac cycle. A leakage into a large vein nto a pulmonary artery may also produce different fects by altering the pressure in these vessels rather than he left ventricle. Despite this there will remain on the rial side certain common manifestations of leakage, the phenomena accompanying such leakage in one dition may illuminate similar phenomena occurring in the er."
>
> Arteriovenous anastomoses, when free, are associated characteristic signs of aortic reflux in the systemic rial system—namely, low diastolic pressure, large pulse sure, collapsing pulse, capillary pulsation, and a difference ne arm-leg systolic pressure."

The statements of Osler, and Lewis and Drury e made after a study of traumatic and experimental arteriovenous fistulæ. The lesion, which must be treated surgically, has many of the signs and symptoms of cardiac disease.

Five Recently Observed Cases.

Congenital arteriovenous fistulæ may present many of the signs of the traumatic. They offer problems, as far as therapy is concerned, which are not encountered in the traumatic variety. The congenital fistulæ also suggest a close relationship to cirsoid aneurysms, rankenangioma, and other types of hæmangiomas encountered in works dealing with surgery and in surgical practice. I should like to discuss the following cases which I have recently observed.

Fig. 1.



Case of phlebectasis reported by Reid. Large dilated veins without any of the signs or symptoms of an aneurysm.

Case 1.—W. R., male, aged 21. This patient entered the Johns Hopkins Hospital Oct. 3rd, 1929. From birth small, painless, collapsible swellings were noted in the right upper extremity of this patient. These increased in size with growth. The location of these and their general appearance may be seen in Figs. 2 and 3. When the patient was about 12 years of age a distinct bruit developed in the extremity which the patient could hear. This bruit has persisted.

Upon *examination* the pectoral region and shoulder on the right side appear larger than on the left. The veins are also much more prominent on this side. A large collapsible swelling is found upon the outer side of the arm just below the deltoid, another in front of the elbow on the inner side, and several in the forearm. A scar is found upon the anterior surface of the forearm just above the wrist on the radial side. At this point one of the large veins which seemed about to rupture was dissected out. Upon palpation a systolic thrill is felt over the suprasternal notch; in the neck as high as the angle of the jaw on the right side, and over the vessels of the arm down to the elbow near a large vein. Here distinct systolic and diastolic thrills are felt. These are felt in the forearm almost to the wrist. A distinct systolic and diastolic bruit is heard over the large purring vessel in front of the elbow. This is transmitted into the forearm. A systolic bruit is heard over the arm, along the vessels

in the neck up to the angle of the jaw on the right side, and below the manubrium.

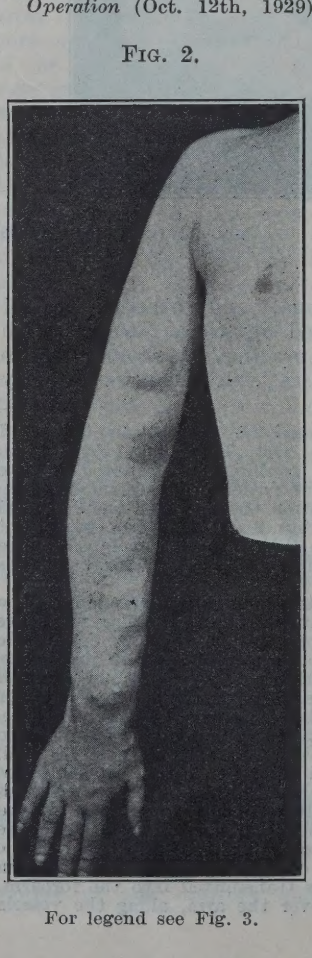
Bradycardiac Reaction.—The heart does not seem to be increased in size, but definite vascular phenomena are noted when the brachial artery is compressed at any point down to the large vein at the bend of the elbow. When the brachial artery is occluded marked slowing of the pulse is noted almost immediately. The initial slowing is accompanied by some irregularity. For example, the pulse would be slowed by 18 or 20 beats when the artery was closed. The pulse decreased in one instance from 89 to 70 beats. This slowing could be elicited at any time. Compression of the large subcutaneous vein at the bend of the elbow in which the machinery-like thrill was felt caused slowing of the pulse, just as did occlusion of the artery. The blood flow in the extremity before the artery was compressed was 3 litres per minute. This is somewhat low. The flow rose to 3·45 litres per minute when the artery was closed. Dr. Harrop, who made these examinations, believes that there is no indication in the case under discussion that the blood flow is slowed after occlusion of the artery which communicates with the veins.

Capillary Pulse and Heart.—A distinct capillary pulse is noted, but the Duroziez sign is not marked. The heart shows no enlargement. The right extremity is one inch longer than the left. An X ray examination of the soft parts shows marked changes. The right radius is perforated by many large vessels. The architecture of this bone is indicated in Fig. 4. It is much altered. A healed fracture in the lower third of the radius is shown. According to the history this fracture occurred without much violence, and was undoubtedly pathological.

Operation (Oct. 12th, 1929).—The brachial artery was first exposed in the internal bicipital pulcus, about three inches above the elbow. The artery was considerably larger than normal. Its walls were thin. The venæ comites were large, but did not pulsate. The brachial artery was doubly ligated. The large vein at the bend of the elbow in which the machinery-like thrill was felt was next exposed. This was an enormously dilated median basilic vein. Approximately five inches of this vein were removed. It was first ligated where the deep communicating branch joins the radial, and was then dissected out proximalward to beyond the point where the superficial ulnar unites with the median basilic to form the basilic vein. The thrill ceased when the brachial artery was ligated, but the median basilic vein and the venæ comites did not collapse. Following the operation the patient complained of considerable pain in the hand. I believe this due to thrombus formation. Thrombi can be distinctly felt at the points where the pain is most severe. An especially large thrombus can be felt on the posterior surface of the forearm about the middle near the radial side.

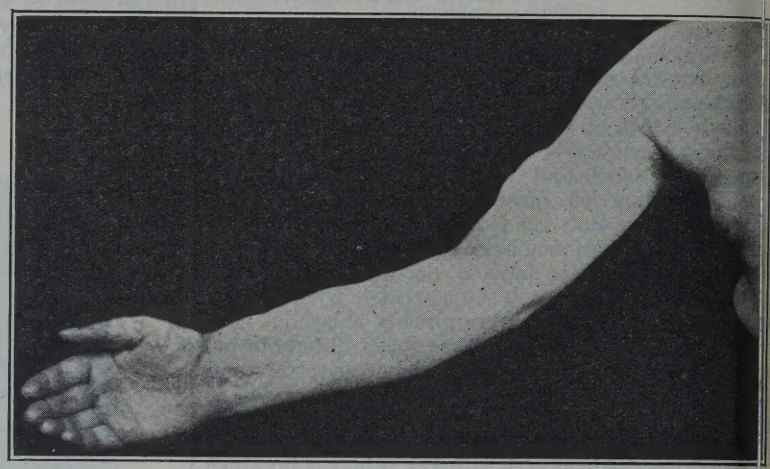
When the patient was discharged from the hospital, Nov. 16th, 1929, a distinct bruit could be heard abo the elbow and over the lower third of the humerus on outer side. A distinct thrill could be felt there. Thrombo had occurred in many of the vessels, even in the sma

FIG. 2.



For legend see Fig. 3.

FIG. 3.



FIGS. 2 and 3.—Photograph of Case 1 in two positions illustrating the locat of the dilated veins. The most intensive systolic and diastolic thrill and machine-like murmur were felt and heard at the bend of the elbow on the antero-internal s Compression of the brachial artery or the large vein was followed by an alm immediate fall in the pulse-rate, the pulse slowing as much as 20 beats. T beginning of slowing was associated with some irregularity.

vessels of the hand. Slowing of the pulse no longer follo closure of the brachial artery by compression. The si associated with an arteriovenous fistula had disappea to a considerable extent. A distinct bradycardiac reac was noted in this aneurysm following closure of the brac artery, but no cardiac changes.

CASE 2*.—A. L., white, female, was admitted to Johns Hopkins Hospital, Sept. 30th, 1925. She stated four weeks before she had fallen and struck her arm aga the corner of a table. After two hours her arm be to swell. Sharp pain was experienced. Later this bec dull and throbbing. The patient also complained of a feeling in the little finger, and when the pain came on she as if she must flex her finger. The right forearm appe larger than the left (Fig. 5), and the skin of the forearm hand was blue. A decided swelling was found on the in side of the upper third of the forearm which extended to lower part of the arm. The swelling is soft and compress and feels like a mass of worms beneath the skin. Within mass are swellings which collapse on pressure. A dist pulsation of the veins is noted. At the bend of the el on the inner side a machinery-like thrill is felt. (Fig. When the brachial artery is compressed the thrill disappe Blood pressure taken in the right arm is 130/90—left, 100 There are no heart changes, and no bradycardiac reac following compression of the artery.

Operation (Nov. 10th, 1925).—The brachial artery exposed in the internal bicipital sulcus in the lower thir the arm, and a rubber armed artery clamp placed upo Two aneurysmal dilatations of the basilic veins and radicles were then exposed. (Fig. 7.) Here the machinery-thrill was of maximum intensity. Posterior to the inte condyle an artery, apparently a branch of the poste ulnar recurrent which communicated with these dilatati was found. This was divided and the veins involved disse away. The thrill disappeared, and there has been no ret A mass of veins is still found in the skin of the arm poster in the lower third. This congenital arteriovenous fis had a small communication. There were no heart cha and no bradycardiac phenomenon following occlusion of brachial artery.

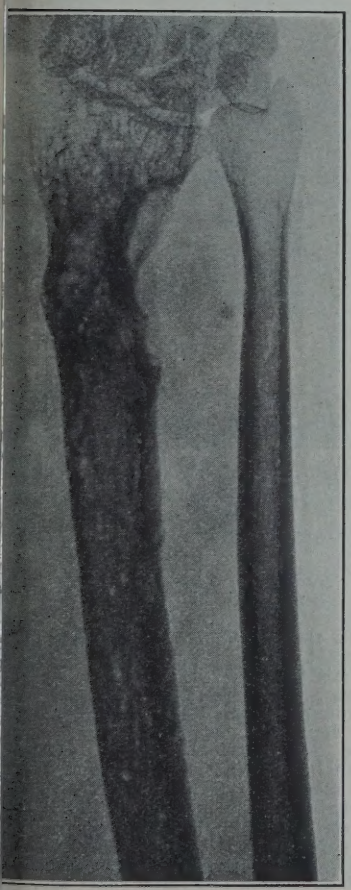
CASE 3.—This patient, a coloured male child, was admi to Harriet Lane Home, April 7th, 1923, when one day At birth a tumour was noted in middle and upper par right arm which presented anteriorly. (Fig. 8.) This vasc tumour extended from just above the insertion of the del down toward the elbow. The tumour is soft, round, wi surface somewhat ulcerated. It is the size of a small tom measuring 6·5 cm. in its greatest diameter. The bas

*This case has been reported—Kongenitale arteriove Fisteln, Deutsch. Med. Woch., 1926, lii., 639.

)vered by normal skin. The surface is apparently covered ith thin epithelium. There is a stellate scar on the surface hich probably resulted from a hæmorrhage which occurred ıortly before the child was born. This mass is soft, almost ıctuant, and changes in size with respiration rather than ith the heart beat.

In the axilla a soft mass of veins is found. The veins are ısily closed by pressure. Beneath the skin, near the tumour, ›e radiating veins of large calibre, which are thrombosed. ıall red macules and telangiectases are seen in the skin ›out the tumour. The apex beat of the heart is in the cillary line 3·5 cm. to the left of the nipple. A harsh ystolic bruit is heard at the apex. It is of maximum tensity here. It diminishes in intensity toward the right de and is not transmitted to the back. This bruit is also eard in the vessels of the neck. As the right axilla is ›proached another systolic murmur is heard. This increases intensity as the tumour is approached. Over the tumour distinct to-and-fro machinery-like murmur is heard. his is transmitted some distance beyond the tumour. There no radial pulse. The extremity is œdematous. X ray :amination reveals a wide mediastinum. To the left of the ediastinum an abnormal pulsation can be made out. This ılsation becomes less marked and finally disappears when ıe brachial artery at the base of the tumour is compressed. The child died three days after admission to the hospital. he autopsy findings were: cavernous angioma of the right m with wide communications between arteries and veins. ›ngenital arteriovenous aneurysm. Dilatation of the teries and veins proximal to the aneurysm. Patent ductus teriosus and foramen ovale; cardiac hypertrophy, œdema the face and neck; generalised lobular pneumonia.

FIG. 4.



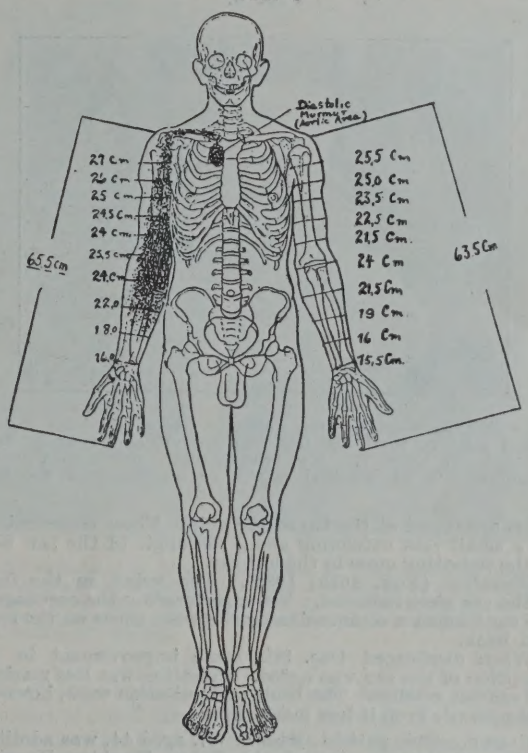
ray of the bones of the forearm of patient mentioned in Figs. 2 and 3. The radius is perforated by many large sinuses. The site of a pathological fracture is indicated in the lower part of the radius. Anastomoses between veins and arteries in these cases render cure difficult, because it is impossible to separate the communications between the veins and arteries in the bone.

The tumour in this case (Fig. 9) suggests a definite relationship between different types of angiomas and congenital arteriovenous fistulæ.

CASE 4.—Dr. Max Ballin (Detroit) has permitted me to report the following interesting case. Since childhood the veins of the dorsal surface of the left hand had been prominent. (Fig. 10.) The middle and ring fingers were puffy and somewhat weaker than the corresponding fingers on the right side. The hand perspired profusely. Dr. Ballin, in writing to the patient's doctor, said, "P. C. is suffering from a so-called cirsoid aneurysm of the middle and ring fingers of the left hand. This is a very interesting condition to me, as I have seen the affection several times. Unfortunately this is quite a serious matter, as the aneurysmal condition usually extends into the whole hand and travels up the arm. We should try to stop the process in Mr. C.'s case by ligating off the communication between arteries and veins in the neighbourhood of the radial artery over the wrist. The communications are usually multiple and sometimes recur. Please note the increased growth in length of the affected fingers, the profuse sweating of the hand, the aneurysmal bruit over the palm and over the radial artery. I would not promise that ligation will stop the process, but it should be tried. It may be that amputation of the two affected fingers will have to be added."

Operation.—A six-inch incision was made over the radial artery from three inches above the wrist to the middle of the

FIG. 5



Indicates difference in size of the two extremities. Dots indicate the distance to which the murmur was transmitted.

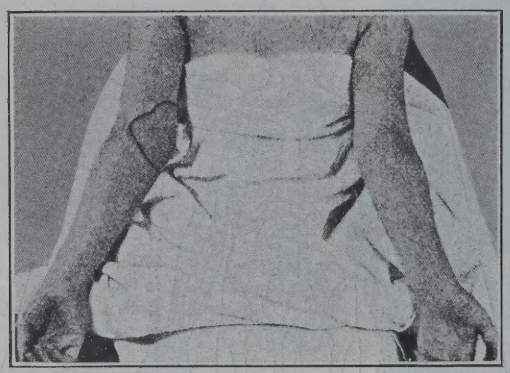
palm. Large cirsoid veins surround and communicate with the radial artery. These communicating branches were isolated and ligated near the artery. The median nerve was well exposed and protected. After the tourniquet was removed, it was noted that, while the pulsations in the veins of the dorsum of the hand are less, the pulsation is marked in the veins of the hypothenar eminence and in the vessels on the ulnar side of the hand. Varicosities were found on the ulnar veins up to the middle of the forearm. These communicated with branches of the artery. The vessels were resected for a distance of about two inches. Pulsation in the large veins on the dorsum and in the palm of the hand, and in the two affected fingers ceased.

This operation did not stop the process, and when the patient was last examined a distinct bruit was heard over the dorsum of the third and fourth metacarpals, and dilated veins were present over the fingers. The final result in this case cannot be given, for the patient can no longer be traced.

CASE 5.—I am permitted to report this case through the kindness of Dr. Charles Bagley, who gave me the notes and performed the operation. R. K., female, aged 26. When 4 years old four small lumps appeared on the left auricle. No history of any injury. Patient noticed that the lesion was collapsible. She noticed that they pulsated. They were painful at times. The masses have grown larger during the past 22 years until now the whole ear is involved. (Fig. 11.) At times the pain is very severe. The pain comes on in paroxysms which seem to be associated with increase in size of the ear. The patient states that it seems as if something had burst. Pulsation of the whole ear is quite marked, and noise from the masses bothers her. Hearing in this ear has been impaired for the last two years. The ear has increased in size much more rapidly during the past two years. She says that she feels dizzy at times. There has been no headache, nausea, or vomiting. The general physical examination is essentially negative, except that the patient is pale and obviously undernourished. The left ear is as large as a fist. The swelling is quite symmetrical, but more prominent posteriorly than anteriorly. The ear is purplish in colour,

tense, and pulsates with each heart beat. The ear is irregular over the external surface and large distended veins can be seen. In front of the ear, just over the temporal artery, is a small pulsating swelling. Another mass is found over the back of the ear which extends over the mastoid process. A bruit can be heard over the ear. When both carotids are compressed the bruit disappears. It persists when either one alone is compressed. Two small, distended, pulsating

FIG. 6.



Area circumscribed by line indicates point at which systolic and diastolic thrill was felt, and systolic and diastolic bruit heard, in Case 2. No bradycardiac reaction followed compression of brachial artery or occlusion of openings.

veins are found at the tip of the chin. These communicate by a small vein extending along the angle of the jaw back to the pulsating mass in the left ear.

Operation (Nov. 16th, 1929).—The veins on the front of the ear were removed. Veins perforating the cartilage of the ear formed a communication between those on the front and back.

When discharged Dec. 9th, some improvement in the condition of the ear was noted. Pulsation was less marked; the ear was smaller. The bruit and pulsation were, however, still present, even if less marked.

CASE 6.—This patient, Miss Z. W., aged 44, was admitted to the surgical service of the Johns Hopkins Hospital,

FIG. 7.

Dilatation of the subcutaneous veins at the elbow-joint is shown in this figure. The communication between the arteries and veins in this case was by a single branch posterior to the internal condyle. This vessel was apparently a branch of the posterior ulnar recurrent artery. This communication was divided and the brachial artery ligated. The signs and symptoms of an aneurysm have disappeared. A mass of subcutaneous veins (hæmangioma) still remain posterior to the lower third of the humerus in the subcutaneous tissue.

Jan. 23rd, 1930, complaining of pain in the right heel of about three years' duration. The family and past histories have no bearing on the case. The patient had noted that the right foot and lower part of the right leg had been larger than the left foot and leg, but had not paid much attention to this. The first definite evidences of discomfort in the foot apparently developed after the patient had been standi some time watching a parade. The symptoms noted th were intermittent attacks of pain, numbness and swelli across the under surface of the right heel. At first the symptoms could be controlled by strapping the ank Gradually the pain increased, and the patient experienced sensation as if she were stepping upon a bee whenever t heel was placed upon the floor. One year after the ons of symptoms a diagnosis of an arteriovenous aneurysm w made, and electrolysis employed with temporary benefit.

Operation (May, 1928).—Brisk hæmorrhage was encounter at this operation, but it is difficult to determine the nature the operation from the history given by the patient. Duri March, 1929, the symptoms recurred. Electrolysis w again attempted with some improvement, but the symptor recurred, and in October, 1929, a more extensive operati procedure was resorted to. A number of vessels were ligat and excised. The scar of this incision is upon the outer si of the foot, extending distalward from the external malleol and anteriorly and posteriorly to it. The swelling benea the right heel has increased considerably since this operatio and the patient has been unable to place her heel upon t

FIG. 8.

Congenital tumour in a child. All signs and symptoms of a aneursym occurred in this lesion. The child also had a co genital heart lesion. Death occurred soon after birth. T history of this patient is given under Case 3.

floor, and pains are frequently felt through the ankle a heel. The pulse-rate varies from 80 to 100. The blo pressure is 158 over 84. The heart is negative. No brad cardiac reaction can be elicited. Some pitting of the rig ankle is noted. The right foot and lower part of the rig leg are distinctly larger than the left foot and leg, a several small angiomas may be seen. A diffuse swellin 5 cm. in diameter, is found beneath the right heel. (Fig. 1 Although tense, this can be collapsed by pressure. T whole mass seems to be raised by systole. A systol and diastolic thrill can be felt, and a systolic and diasto bruit heard over this mass. The bruit has a rather sha piping or whistling character. A small angioma is fou on the back near the scapula on the right side.

This case presents some interesting features. Evident changes in the leg and foot were noted from birth. Pain a discomfort in the foot developed but three years ago. O might be justified in concluding from the symptoms th an angioma was present from birth, and that the arteri communication was established but three years ago. Th followed standing for some time watching a parade. The ca also suggests the intimate relation which may exist betwe angiomas and congenital arteriovenous fistulæ. The brui can no longer be heard when the vessels behind and abo the external malleolus are occluded.

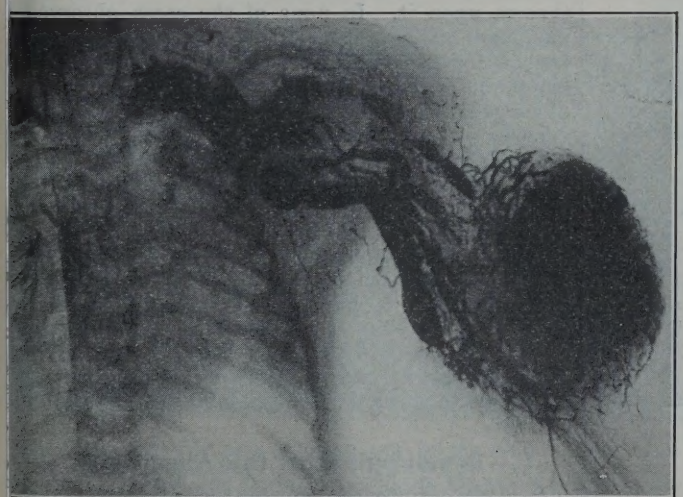
In this group of cases are found most of the clinic phenomena and peculiarities of congenital arteri

enous aneurysm. In the first case the bradycardiac eaction which follows occlusion of the artery, whose ranches communicate directly with the veins, or the losure of the communications between arteries and eins, was striking. In the second case no radycardiac reaction was noted. In oth the second, third, and sixth cases he relationship between hæmangiomas nd congenital arteriovenous aneurysms s suggested. The destructive nature of ome lesions of this type is illustrated by he fourth case. The fifth case presents he clinical picture of this type of lesion ccurring about the head and face, to hich the term cirsoid aneurysm is equently applied.

The Bradycardiac Reaction.

Not infrequently Branham is given the redit of having first observed the marked owing of the heart which follows occlu- on of the principal artery which supplies congenital arteriovenous aneurysm or ie communicating openings. Nocoladoni, n an article entitled "Phlebarteriectasie er rechten oberen Extremität," published n 1875, mentions very definitely the owing of the pulse which follows closure f the principal artery, branches of which ommunicate directly with the veins with- ut intervention of capillaries. This henomenon is also described by Israel in n article published in 1877, entitled Angiectasie in Stromgebiete der arteria ibialis antica." He states that digital clusion of the femoral artery caused the ulse to drop from 108 to 66 beats per minute, ith considerable increase in arterial pressure roximal to the point of occlusion. The heart's ction also became somewhat irregular. When the

FIG. 9.



X ray of injected specimen indicating the relation of the vessels found in the lesion represented in Fig. 8. This case suggests the relation which may exist between the different types of angioma and congenital arteriovenous aneurysm. Rich communication between arteries and veins is shown.

xtremity was raised, so that the amount of blood owing through the aneurysm was reduced, the pulse ropped from 92 to 54.

In both of these communications the bradycardiac reaction is definitely mentioned. Branham's description of this phenomenon was made in 1890. Nicoladoni's description preceded this by almost fifteen years. Various explanations have been given of this phenomenon. The reaction depends upon the amount of blood that is shunted through the aneurysm. If the communication is small the phenomenon will not be observed. If large or many, the phenomenon will be observed, and the congenital type of arteriovenous aneurysm does not differ in this respect from the traumatic. Lewis and Drury came to the following conclusions concerning this phenomenon in their study of the traumatic variety. Their conclusions are expressed as follows:

FIG. 10.

The history of this patient is given under Case 4. Dilatation of vessels on the back of the hand is marked. Some of the signs of an aneurysm persisted after operation. The patient was finally lost track of, so that final result cannot be given. This case is published through the kindness of Dr. Max Ballin, of Detroit.

> "Dealing with the phenomenon observed—namely, conspicuous fall in rate on closing the anastomosis. This fall is vagal in origin, for it is abolished by atropinisation. We are justified in concluding that it is wholly vagal, for at the height of the atropine reaction in the case tested the pulse-rate was altered by but two beats per minute on closing the anastomosis. This slight difference is sufficient to be explained by incomplate paralysis of the vagus by the drug."

Naun has recently made a similar observation. The rise of rate in opening the anastomosis is to be ascribed to a fall of vagal tone. But compression of the artery leading to the aneurysm was ascertained in two of our patients to produce no fall of venous pressure and decompression was ascertained to produce no rise of venous pressure. The changes of heart-rate on compressing and decompressing the artery cannot be ascribed therefore to altered venous filling, but must be attributed mainly to altered arterial pressure. With the last they are very closely associated. When the leak is closed, the lowest pulse-rate is reached within a few heart cycles of the

act of compression. It is at this phase that the systolic arterial pressures rise to their highest. The lowest heart-rate is not long maintained, neither is the highest arterial pressure, both are fleeting; but as this systolic pressure also rises a little or remains unchanged, the arterial pressure change may be viewed as a rise of mean pressure. That a rise of mean arterial pressure retards the heart-beat was first shown by Marey; the effect is generally acknowledged and is ascribed to the vagus.

Lewis and Drury, in summing up, state that:

"in arteriovenous aneurysm the pulse-rate is higher than normal, and this rapid heart action is due to changed vagal tone, controlled through the medium of mean arterial pressure. These observations provide us with a simple explanation of the increased heart-rate which is generally recognised to occur in aortic regurgitation; for the same factor, low mean arterial pressure comes into play in these cases also. When an arteriovenous aneurysm has become established the initial rapidity of the heart's action appears to be in a measure checked, for the rates on closing the leak are lower than normal; probably the same is true in aortic disease."

FIG. 11.

Arteriovenous aneurysm of left ear. Considerable improvement has followed extirpation of veins on the anterior surface of the ear. History given under Case 5. Reported through the courtesy of Dr. Charles Bagley, of Baltimore.

Cardiac Enlargement.

Cardiac enlargement was also noted in aneurysms of the congenital type by Nicoladoni and Israel. In Israel's case the patient was a child, 9 years of age. It is stated that following the amputation for gangrene, following operative interference on the femoral artery, the femoral arteries have become alike, that the right external iliac which was before the operation tortuous, cirsoid and much dilated, differs from the normal artery on the left side only by increased pressure, and that the dilated heart has becor smaller in all diameters.

It will be seen, therefore, that cardiac enlargeme may occur in the clinical picture of this type aneurysm. Cases have been reported by Nicolado Israel, Steinheil, Emanuel, Simmons, Perthes, Pusc and others. The objection might be raised that some of these cases the cardiac changes were seconda to high blood pressure, coronary sclerosis, or emph sema; but enough cases have been observed in whi the heart has returned to normal after the operatio to justify the conclusion that the cardiac chang are dependent upon a disturbed vascular mechanis Leriche extirpated a traumatic arteriovenous aneurys in a patient with enlargement of the heart and sig of decompensation. After the operation the hea returned to normal and the signs of decompensati disappeared. A similar case has been observed Hoover and Beans. The case observed by Israel h already been cited.

According to Lewis and Drury:—

"The cardiac change may be due to a diminished blo flow through the nutrient vessels of the heart. If we take t supply to our limbs as our index, then the flow through t coronary vessels may be diminished by an arteriovenc aneurysm to even one-half of its normal amount. Moreov Markewalder and Starling have brought evidence to sh that the flow in the coronary vessels is peculiarly depende upon aortic pressures; that being the case, the fall of me arterial pressure is of even greater consequence to t metabolism of the heart than it is to the metabolism of t body generally. A dilatation of the heart consecutive to t formation of a free arteriovenous anastomosis appears to u natural sequence."

The cardiac changes may be the direct result of t circulatory disturbances associated with the congenit arteriovenous aneurysm. In some there are cardiac changes. In these not enough blood shunted directly into the veins to produce the changes, the anastomosis or anastomoses bei relatively small. It has never been determined h much blood must be shunted directly into the vei to cause this change. Congenital arteriovenc aneurysms occur in the young, and the heart may able in these cases to take care of the increased wo thrown upon it. In none of the cases observed me has cardiac hypertrophy or decompensati been a marked feature of the clinical picture. Th statement also applies to the cases observed by Dan of congenital arteriovenous aneurysms of the cerebr vessels.

There is abundant evidence to prove that cardi hypertrophy and decompensation may follow traumat arteriovenous aneurysm. Cazanian noted that hypertrophied heart diminished in size followi successful operation. That dilatation is the ma element in the enlargement is clearly evidenced the rapidity with which the size decreases when i cause is removed; thus Naun and his collaborato noticed the change to occur within a few weeks the operation in two cases. Similar rapid return the heart to normal has been observed in a numb of cases.

Development of the Aneurysm.

In many of the cases reported the signs and sympton of an arteriovenous aneurysm were not present birth. In Cases 1 and 6 of the series no reported the signs of an aneurysm, according to t statement of the patient, did not appear until t patients were 13 and 41 years of age respectivel There is a possibility in all of the cases that the sig were present but not noted. In other cases t signs and symptoms have developed, according the patient's statement, after a strain or injury b

lunt force. In none of the cases, however, has nere been a penetrating wound; therefore, the ossibility of the traumatic variety of arteriovenous neurysm can be excluded.

Rienhoff states that:—

congenital arteriovenous fistula is a very rare condition, ut a definite clinical syndrome which has been confused in ne past with other congenital anomalies of the blood ascular system, such as aneurysm by anastomosis, cirsoid neurysm, nevus maternus, pulsating nevus and venous neurysm. In consideration of the mode of development of the lood vascular system, and in view of the fact that in one xperiment an arteriovenous fistula was observed in formation, 'e feel that congenital arteriovenous fistula occurs as the sult of the persistence of vessels or communications of ne primary anlage, which, failing to develop into the ormal definitive vascular tree, results in the formation of nastomotic channels either directly or indirectly between therwise normally developed arterial and venous trunks."

Apparently the abnormal communications may be stablished after birth, either spontaneously or as ne result of some injury in which the vessel walls ave not been penetrated. This statement is made fter eliciting a careful history of patients under bservation and studying cases which have been eported. If there is a direct end-to-end communica- on between the vessels, the lesion may resemble a umour in its rapid enlargement and destructive haracter. The enlargement will be considerably ss rapid when the arteries and veins are connected y small lateral communications. The communication etween the arteries and veins without the intervention f a capillary bed gives the distinct characteristics of sions of this type, and differentiates them from other ascular tumours clinically. Many of the vascular umours are potentially congenital arteriovenous neurysms, however, for at any time the direct ommunication between the arteries and veins may e established spontaneously, or as the result of n injury in which the skin is not penetrated.

Reid believes that cirsoid and arteriovenous neurysms are alike in many other respects. Ætio- gically, trauma and congenital anomalies are

FIG. 12.

welling beneath the heel indicates site of the lesion. This mass has a heaving pulsation, which is transmitted from some distance below. A systolic and diastolic thrill can be felt and a machinery-like murmur heard over the mass. No bradycardiac reaction can be elicited. There are no cardiac changes. Dilated veins may be seen in the skin. History given under Case 6.

roductive of both conditions. Trauma is by far ne most frequent cause of arteriovenous aneurysms; is probably the most frequent cause of cirsoid neurysms. Many of them have followed a blow on ne head, and most of the cirsoid aneurysms occur this region. In this very vascular region, where the bone is near the surface, blows might easily establish an anteriovenous communication, taking the form of a cirsoid aneurysm. Indeed many of the so-called congenital cirsoids of the head may have had their origin in the pressure exerted on the skull at birth. Clinically, both conditions lead to enormous dilatation and pulsation of the involved veins and proximal arteries. After a study of his own and reported cases, Reid says that he cannot escape the conclusion that there is no difference between cirsoid aneurysms and arteriovenous aneurysms, except that the term cirsoid aneurysm has been applied to that condition which results from abnormal venous communications which occur in the more peripheral and smaller vessels.

FIG. 13.

Arteriovenous aneurysm of base of brain. Many large tortuous veins are seen (Dandy).

Granting that the above contentions are true, it must be assumed in most cases that there has been an anomaly in the blood vascular anlage which permits of the development of this peculiar lesion when the essential causative factors, such as blunt force or a spontaneous communication between the arteries and veins are operative. That a communication may be established relatively late between anomalous arteries and veins would seem to be well shown in arteriovenous aneurysms of the brain. In 44 per cent. of the cases in Dandy's report, the first symptom did not appear until after the age of 30, and in 30 per cent. the symptoms began after the fortieth year. The latest appearance was at the age of 48. If we may assume that the symptoms were associated with the aneurysmal changes in vessels in which an anomaly was present, the communication between the arteries and veins did not develop until late.

According to Dandy, two types of arteriovenous aneurysms occur in the brain. In one an anomalous vessel of congenital origin established a direct end-to-end communication between an artery and vein;

in the other a net-work of vessels—so-called angioma—is interposed between an artery and one or several veins. Both types are characterised by large, full and tortuous veins on the surface of the brain. (Fig. 13.) A thrill can usually be felt, and red arterial blood can be seen in the dark venous blood. Congenital anomalies are usually found in the veins on the surface of the brain. Arteriovenous aneurysms of the brain are not uncommon, occurring, according to Dandy, in about 1 per cent. of a series of brain tumours. It seems to me that this class of arteriovenous aneurysms indicates more clearly than any other that the anomaly in the vascular anlage, which later gives rise to the aneurysm, is congenital, and that the communication between the arteries and veins may be established later, and in the brain spontaneously. Such spontaneous communications also develop in the extremities.

(To be concluded.)

COG-WHEEL BREATHING.

By G. T. Hebert, M.D. Oxf., M.R.C.P. Lond.,

PHYSICIAN IN CHARGE OF THE TUBERCULOSIS DEPARTMENT, ST. THOMAS'S HOSPITAL, LONDON.

The following paragraph appears in a well-known handbook [1]:—

Jerky, Interrupted, or Cog-wheel Inspiration.—Here the sound is not continuous, but occurs in waves or sharp jerks. This indicates irregular expansion of the alveoli, due to unequal elasticity in various parts of the lobules, and is therefore not infrequently present in early tuberculosis. It may result, however, simply from nervousness, and to carry any weight as a physical sign it must be well marked even on deep inspiration. Even then, however, it may mean little or nothing, and should only take a very secondary place.

Again, according to Powell and Hartley,[2] cog-wheel breathing may be due to irregular action of the respiratory muscles, to hysteria, or to textural diseases of the lungs, or may be produced by cardiac pulsation; and in their table of physical signs [3] its significance is given as "irregular expansion of lung from partial consolidation around small bronchi; but often of purely nervous origin through irregular contraction of muscles." American authors [4 5] express similar views. In other words, the general opinion seems to be that cog-wheel breathing has sometimes a pathological, sometimes a functional, and sometimes a physiological origin; that at times it indicates early tuberculosis, and at others has little or no significance.

Study of 1000 Cases.

In order to attempt to clarify the position and to assess the value of cog-wheel breathing as a physical sign, a study of 1000 cases was undertaken, consisting of 428 adult males, 409 adult females, and 163 children under 16. In 292 of these pulmonary tuberculosis was diagnosed, while in the large majority of the remaining 708 no lung lesion was apparent.

The inquiry emphasised the fact that cog-wheel breathing, as defined above, is of two kinds. In one the interruptions are irregular; in the other they are regular or, to be more exact, they are synchronised with the beat of the heart. Breathing of the first type is uncommon, and is rarely, if ever, heard a well-marked waves or sharp jerks. In none of th 1000 cases could it be ascribed to a pulmonary o pleural lesion, and, on the few occasions on which i was heard, it was noticeable only when the patien was breathing forcibly. The writer holds that fo testing the quality of breath sounds forcible respira tion should not be used, and, if this rule is adhered to irregularly interrupted breathing is so rarely hear that it ceases to be of any importance for clinica purposes. Breathing of the second type, on th other hand, is by no means uncommon and can a times be a very striking feature. The description an figures given below refer only to this second, o regular, type, which would appear to be merely physiological phenomenon, and for which "air waves" is the most suitable term.

DESCRIPTION OF AIR-WAVES.

Air-waves are heard during inspiration, but onl rarely during expiration. Though synchronised wit the beat of the heart, and systolic in time, they ar breath sounds not heart sounds, for they cease whe the breath is held (or during expiration) and th heart sounds may then be audible in their place Their number during an inspiration varies with th pulse- and respiration-rates, but usually at least tw or three waves can be heard. Their intensity varie in different patients from a series of sharp hissin sounds with short intervening pauses to barel perceptible rhythmical increases in the inspirator sound, but is constant for any particular patient Certain factors, particularly the force of the cardia impulse, may affect their intensity but under simila conditions they remain the same from day to day They are heard best near the angle of the left scapul or in the axilla, and sometimes only over a sma area and after careful search. If present here the may in some cases be heard round the border of th heart in front, particularly just outside the apex, o over the greater part of the left lung, or sometime on the right side as well. They are less obviou during deep inspiration, but appear to be mor obvious in cases of fibrosis.

FREQUENCY.

In the 1000 cases investigated, air-waves were no considered to be present unless at least at one plac their cardiac timing could be recognised. Under th ordinary conditions of examination, and without an attempt to reinforce them, they were found in 12 (30 per cent.) of the adult males, in 217 (53 per cent of the adult females, and in 31 (19 per cent.) of th children under 16. In each successive 100 case examined there was rarely more than a 10 per cent difference from these figures.

RELATION TO TUBERCULOSIS.

The following table shows that the percentages o cases with air-waves were decidedly higher in th tuberculous than in the non-tuberculous:—

—	Non-tuberculous cases.			Tuberculous cases.		
	A.m.	A.f.	C.	A.m.	A.f.	C.
With air-waves ..	69	123	27	58	92	4
Without air-waves	211	150	128	90	136	4
Percentage with air-waves	25	46	17	39	68	50

A.m. = Adult males. A.f. = Adult females. C. = Children.

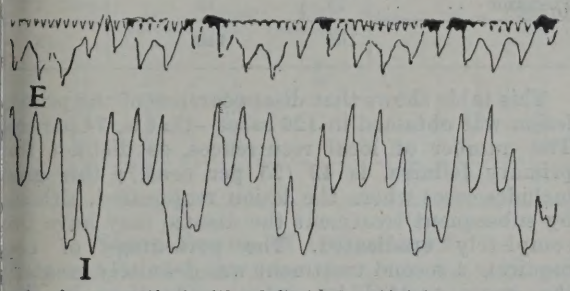
The difference is probably of no significance, for th

[1] Hutchison, R., and Hunter, D.: Clinical Methods, London, 1929, p. 302.
[2] Powell, R. D., and Hartley, P. H.-S.: Diseases of the Lungs, 6th edition, London, 1921, p. 52.
[3] Ibid., p. 40.
[4] Fishberg, M.: Pulmonary Tuberculosis, Philadelphia, 1922, p. 341.
[5] Norris, G. W., and Landis, H. R. M.: Diseases of the Chest, 4th edition, Philadelphia, 1929, p. 129.

tuation of the air-waves bore no relation to the site r character of the lesion, and probably is to be ccounted for by a generally more forcible cardiac ction in the tuberculous. The same factor, but aused in this case by nervousness, no doubt accounts or a percentage of air-waves of 64 in non-tuberculous omen between the ages of 16 and 25, as compared ith that of 37 for non-tuberculous women over 25.

CAUSE.

The situation and the timing of air-waves make probable that the heart, and particularly the left entricle, is intimately concerned in their production. would suggest that the contraction of the heart auses a compensatory expansion of the adjacent art of the lung so that it expands in a series of rks, with a corresponding effect on the inspiratory rrent of air and the breath sounds. Before such a eory can be accepted, it must be proved (1) that an crease of the intrathoracic negative pressure occurs ith each cardiac systole, (2) that the current of air ltering the lungs undergoes periodic acceleration,



acing from a patient with a left-sided artificial pneumothorax. The upper record is from the cardiac impulse on the chest wall, the lower from the pneumothorax. In the latter, expiration is marked E and inspiration I. The highest expiratory and lowest inspiratory pressures were 13 and 5 cm. of water, respectively. The tracing, to be read from left to right, shows negative pressure waves in the pneumothorax during inspiration and expiration, synchronous with the beat of the heart.

) that forcible action of the heart increases air-aves, and (4) that expiration is affected similarly to spiration.

1. An investigation of changes of pressure in the thorax as made in a series of patients undergoing artificial pneumo-orax treatment. Using the metal manometer of the eaf's apparatus, which is more sensitive than the water anometer of the Lillingston and Pearson model, it was und that in all cases a reduction of pressure occurred in e pneumothorax with each cardiac systole. These reduc-ons were approximately the same during expiration and spiration, they were slight in the right-sided cases, they ere larger when the collapse of the lung was complete and hen the mediastinum was rigid, and they amounted to a gative pressure of 3 or 4 cm. of water in some left-sided ses in which well-marked air-waves had been heard fore the pneumothorax was induced. Some records were ade with a polygraph.

2. Pressure fluctuations, which presumably would result alterations of velocity, were demonstrated in the inspira-ry and expiratory currents of air by attaching the mano-eter to a lead from the tubing of a Douglas mask; and replacing the manometer by a polygraph, the synchronisa-on of the respiratory waves with the apex thrust was own. In many cases waves can be heard in the trachea the patient takes a long slow breath.

3. In several patients the effect of exercise on air-waves as tested. It invariably increased their audibility or, in me cases, rendered them audible when they could not be ard under normal conditions. A few cases of valvular sease of the heart with hypertrophy were examined, but increased tendency to air-waves was noted.

4. The tests just mentioned in paragraphs (1) and (2) show at pressure fluctuations occur in expiration as well as in spiration, though air-waves are not often heard in the rmer.

Finally, the question arises: If air-waves are a ysiological phenomenon, why cannot they be heard in every individual? The investigation showed that air-waves differ in intensity in different cases. In some they are well marked, in others barely recognisable, and in others inaudible even after exercise. Yet pressure fluctuations were recognisable in the pneumothorax of all of the cases tested and it is reasonable to suppose that air-waves, inspiratory and expiratory, could be heard in all individuals if the auscultatory test were sufficiently sensitive.

DIFFERENTIAL DIAGNOSIS.

Certain sounds with a cardio-respiratory timing can occasionally be heard, the commonest of which are exocardial murmurs, pleuro-pericardial friction, and certain vascular murmurs. Hutchison and Hunter [6] describe an exocardial murmur as follows:—

> A soft systolic murmur of exocardiac origin is occasionally audible near the apex of the heart in cases of pulmonary tuberculosis; it is often propagated towards the axilla just as a mitral systolic murmur would be, but may be distinguished by its ceasing to be heard over the heart itself where uncovered by lung, and by disappearing or altering markedly in character when the patient holds his breath. Such cardio-respiratory murmurs must not be mistaken for the true endocardial ones.

The possible explanation of such murmurs on the basis of air-waves should always be borne in mind. At least four of the 1000 cases investigated had been diagnosed as cases of heart disease on account of a systolic murmur heard to the left of the apex of the heart during inspiration. As none of the four had symptoms of heart disease and all had well-marked air-waves over the left lower lobe posteriorly, it is almost certain that the so-called murmur was also a respiratory sound. Similarly, some cases of so-called pleuro-pericardial friction are merely instances of air-waves, and are respiratory sounds not friction sounds. In two of the 1000 cases a definite pleural friction sound at a distance from the heart had a cardiac timing during inspiration, while air-waves could be heard over adjacent parts of the chest wall. On the other hand, murmurs may be heard during inspiration over the upper part of the chest in front which are certainly not air-waves. The commonest is that heard just below part of the clavicle on either side. It is a vascular murmur from the subclavian artery, heard towards the end of inspiration when the vessel has descended with the apex of the lung and has come within the range of the stethoscope.

Conclusions.

1. Cog-wheel breathing is of two kinds. In one the interruptions are irregular, and are due probably to irregular action of the respiratory muscles. In the other they are regular, have a cardiac timing, and are best termed air-waves.

2. Air-waves were found in 30 per cent. of adult males, in 53 per cent. of adult females, and in 19 per cent. of children under 16 in 1000 cases investigated.

3. Air-waves are not caused by tuberculosis of the underlying lung tissue, but are a physiological phenomenon.

4. Their situation and the demonstration of pressure fluctuations, synchronous with cardiac systole, in the pneumothorax cavity of some patients and in the inspiratory and expiratory currents of air of others, suggest that they are caused by an expansion of the lung compensatory to the contraction of the heart.

5. Certain cases of so-called exocardial murmurs and of pleuro-pericardial friction are probably merely instances of air-waves.

RADIUM TREATMENT OF CANCER OF THE TONGUE.*

By Stanford Cade, F.R.C.S. Eng.,
ASSISTANT SURGEON, WESTMINSTER HOSPITAL.

Radium treatment of cancer of the tongue has made rapid strides in the past few years, following the results obtained by Regaud, who introduced the method of needling now in most general use. A period of exaggerated enthusiasm followed, and, unless a period of unjustifiable pessimism is to come, it is essential from time to time to review the position of this relatively new method.

Selection of Cases.

The time for comparing and contrasting radium with surgery has passed, so far as the immediate results are concerned, and the possibilities of radium are now universally recognised; but a comparison of end-results is more difficult to assess accurately because operability is of far greater importance in excisional treatment than it is in radiotherapy. Radium as a method of treatment is applicable in cases totally unsuitable for excision and, in the study of the list of cases to follow, no attempt is made to separate the operable from the inoperable group; stress is, however, laid upon the glandular condition. All cases were treated with the exception of those actually not expected to survive more than a few weeks. The chief object in view was to alleviate the patient's condition, even if nothing more than palliation was anticipated. The selection of cases makes a vast difference in the percentage of final results, but we were less concerned with the brilliancy of eventual statistical tables than with the attempt to treat all cancerous patients seeking advice; and in this way from time to time an entirely unexpected result was obtained, which was nothing short of a miracle. This was perhaps a factor mercifully provided by chance in an otherwise dismal procession of patients, the majority of whom were rejects from other institutions and were well beyond the range of even the most courageous of surgeons.

All the cases were treated by implantation of radium needles into and around the tumour, seeds being used exceptionally when local conditions demanded it. The needles used contained 0·6 mg. and 1·3 mg. of radium, and were fully screened by 0·5 mm. and 0·6 mm. of platinum respectively. The period of treatment was seven days. The amount of radium used depended upon the extent of the disease. Treatment of the primary lesion was nearly always followed by treatment of the lymphatic area in the neck. Only in the first two years was this occasionally omitted, generally in cases where nothing abnormal was palpable. This policy proved disastrous and was soon abandoned in favour of systematic treatment of the lymphatic areas in all cases.

Analysis of Results.

The statistical tables submitted are based upon a total of all my own cases treated at Westminster Hospital, in private and elsewhere, and upon the cases treated by my colleagues at Westminster Hospital. They cover the period of five years from April, 1925, to April, 1930. There is no selection of cases; the few not submitted to treatment are not included in the tables. Those that could not be traced are considered as having died three months after their last visit to the hospital. The remainder of the cases have been traced and seen, or the doctors communicated with. A suspicious induration is considered as a local recurrence, unless excised and proved to be non-malignant on histological section.

Oral Cancer.—The total number of cases of oral cancer treated is 253; distributed as shown in Table I.

Table I.—*Total Cases of Oral Cancer.*

Tongue	169	Palate	8
Cheek (buccal mucosa) ..	23	Lip	1
Tonsil	12		

Lingual Cancer.—The total number of cases of lingual cancer is 169, distributed as in Table II.

Table II.—*April, 1925, to April, 1930: Five Years.*

Carcinoma of tongue.	Total.	Disappearance of primary growth.	Local recurrence
Anterior	20	15	7
Antero-lateral ..	79	65	21
Postero-lateral ..	14	9	2
Inferior	33	25	9
Posterior	23	12	4
	169	126	43

This table shows that disappearance of the primary lesion was obtained in 126 cases—that is, 74 per cent. The number of local recurrences, as distinct from primary failures, is 43 (25 per cent.); this group includes cases where the lesion reappeared, although by subsequent treatment the disease may have been completely eradicated. The percentage of cases requiring a second treatment was definitely greater in the group treated by radon seeds than in those treated by needles. In some cases local recurrence were obviously due to under-dosage and, as experience increased, this group of cases became smaller. The local recurrences must be carefully distinguished from ulceration at the site previously occupied by the primary growth which may be due to sepsis, excessive irradiation, and a delayed radium reaction, specially in areas involving the mucosa covering the gum, where an underlying necrosis of the bone may not become evident till a few months later. The percentage of local recurrences can be minimised by removing with the diathermy needle all suspicious indurations, residual nodules of thickened tissue although these may only be due to fibrosis. The local condition of the area previously occupied by the neoplasm must be soft, resilient, and covered with intact mucous membrane. With adequate screenage, suitable dosage, uniform distribution of the needles, strict aseptic precautions, and preliminary oral hygiene, including the removal of teeth, this can be achieved in the majority of cases.

Survival-rate.

Table III. shows the survival-rate in the cases treated in each year. It shows only two cases alive out of a total of 18 cases treated in 1925. But this list must be studied in conjunction with Table IV.

Table III.—*Survival-rate.*

Year.	Total cases.	Alive to-day and percentage.	Years of survival
1925	18	2 (11)	5
1926	16	3 (18·7)	4
1927	23	6 (26·5)	3
1928	33	16 (48·4)	2
1929	47	30 (63·8)	1
1930	32	16 (50)	Less than one.
Total..	169	73 (47·9)	—

* Read at the Section of Surgery of the British Medical Association's meeting at Winnipeg, Canada, reported on p. 638

which shows that of the 18 cases 13 had palpable glands, and in seven of these the glands were surgically removable; this leaves five cases with no palpable glands, of which two are alive at the end of five years. It has already been stated that in the early days the treatment of the neck received only scanty attention, so that, although these five cases were early, some of them had no treatment to the lymphatic area till it was too late and eventually died from metastasis.

Table IV. shows the number of cases treated in each year, those with lymphatic involvement and those where the glands were inoperable. The percentage of survival for less than one year in 1930 is 50 per cent.—that is, less than the one-year survival for 1929, and can be explained by a marked increase in hopeless cases treated as more accommodation for patients was provided.

TABLE IV.—*Glandular Involvement and Rate of Survival.*

Year.	Total cases.	Glands		Survival in years.			
		Involved.	Inoperable.	Five and four.	Three.	Two.	One or less.
1925	18	13	7	2	3	1	2
1926	16	14	9	3	4	2	7
1927	23	22	11	—	6	5	12
1928	33	24	15	—	—	16	17
1929	47	33	23	—	—	—	30
1930	32	24	18	—	—	—	16
Total	169	130	83	5	13	24	84

Some Points of Importance.

The experience gained by the treatment and the study of after-results of these 253 cases has led to a better understanding of the disease, to some improvements in the methods of treatment, and to a more thorough attack on the glandular area. The lessons learned are summarised below.

TREATMENT OF PRIMARY LESION.

(*a*) Needles are preferred to seeds as more accurate distribution is possible and there is less likelihood of leaving non-irradiated areas and so possible sites for future recurrences.

(*b*) The impression that results are more permanent with radium salt than with emanation is based upon actual cases, and is possibly due to the uniform intensity being maintained through the whole period of treatment with the former.

(*c*) Screenage by 0·6 mm. of platinum is preferred, as this allows the treatment to be continued for seven to ten days without marked risk of necrosis.

(*d*) Re-needling of the tongue at the end of the first week is practised in extensive lesions and is referred to larger dosage left in for seven days only.

(*e*) Cases of posterior carcinoma can be needled by open operation through a pharyngotomy with great accuracy and good result. Peroral needling is less accurate and should be reserved for the more insensitive type of tumour (the transitional-celled carcinoma of Quick or lymphocarcinoma of Regaud).

PROSTHETIC APPLIANCES.

(*a*) Lead protection of the roof of the mouth is practised in every case where the amount of radium in the tongue exceeds 6 mg. (10 needles of 0·6 mg. or its equivalent). The protection is not always necessary, but is a safeguard against radium burns of the palate which have occurred in non-protected cases.

(*b*) Lead protection of the floor of the mouth is not used as a routine, but only in cases where the disease is entirely localised to the tongue and does not involve the floor of the mouth.

(*c*) Plates made of stent or vulcanite or composition are used to help to retain the needles in the floor of the mouth. These plates do not contain lead.

(*d*) Surface application to the tongue is not practised. In cases too advanced for needling, seeds are used and glossectomy by the diathermy is considered.

Treatment of the Cervical Area.

No neck should be left untreated, even if no glands are palpable, and the lesion in the tongue is small, the gravity of possible extension to glands is such that treatment cannot be omitted. In certain histological types and in patients under 50 years of age the prognosis entirely depends upon the early and vigorous treatment of the neck. The policy at present advocated is to divide the cases into three groups—namely: (1) unpalpable glands, (2) palpable glands, and (3) inoperable glands. The treatment differs in each group.

UNPALPABLE GLANDS.

This group is suitable for needling of the neck by the "closed method." The distribution of the needles must be accurate, extending from the mastoid process to the clavicle and providing efficient irradiation in the submental, submaxillary, anterior, and posterior triangles of the neck. With a little experience the needles can be placed in position without an operation for access. As an alternative to this method a radium collar can be employed, but as the treatment is entirely a prophylactic measure, a two-stage irradiation is not indicated. Needling is, as a rule, preferred by the patient, as it is somewhat less irksome than surface application.

PALPABLE GLANDS.

When the glands are palpable but small, mobile and absolutely operable, the choice of treatment lies between operative removal and "open needling" after providing access to the glandular area by surgical means. Surgical removal of the glands is only indicated if the following conditions obtain:—

(1) The primary lesion must have entirely disappeared.
(2) The glands must be absolutely operable.
(3) The general health of the patient must be good.

If the operation for the removal of the glands is undertaken, it must be a complete and wide excision. Half measures have no place in the treatment of the cancerous neck; an incomplete operation leaves the patient in a worse plight than before the treatment and must never be done, as irradiation offers so much more. The operation is variously known as Butlin's, Crile's, or "block" dissection, and is sufficiently well known not to require a description here.

The insertion of radium in the neck at the end of the operation is not advisable, and irradiation is much more efficiently carried out as a second stage by means of a columbia paste collar after the wound is healed.

If the surgical removal of glands is not undertaken the neck is needled by the "open method." Insertion of needles blindly into the neck in cases where the glands are palpable, but early and discrete, is not advisable; more freedom and, hence, greater accuracy is obtained by incising the neck along the sterno-mastoid, exposing both its anterior and posterior borders, dividing the common facial vein at a short distance from the internal jugular, and placing the needles in position under vision in close proximity to the enlarged glands; the submaxillary and submental areas are also needled.

INOPERABLE GLANDS.

When the glands are matted together and a fixed mass is present in the neck, palliation only is aimed at.

It is obtained by needling the mass and the surrounding tissues with a relatively large quantity of radium; the technique of needling in this case differs from that in the group dealing with palpable glands. The mass is literally filled with radium; seeds can be used here, and screenage is of lesser importance as the mass of tissue itself acts as a protection. It gives remarkal results at times. The interstitial method is follow two or three weeks later by surface application the whole neck. The future will show if distan applications with the "bomb" will give better resu than the methods here described.

CLINICAL AND LABORATORY NOTES

RAYNAUD'S DISEASE,

WITH PAROXYSMAL HÆMOGLOBINURIA.

By Harold G. Bywater, M.B., Ch.B. Liverp.,
RENAL SPECIALIST, MINISTRY OF PENSIONS, NOTTINGHAM.

Six months ago a child, aged 3 years, was taken ill after being aroused from sleep suddenly in the middle of the night and very much frightened by the intrusion of a drunken man into the house.

He had previously been in good health as far as the parents were able to judge, his only illness having been measles in infancy. He had been fed on Cow and Gate food. The mother had had one previous miscarriage and had subsequently had one other child, who appeared to be in good health. The father, who had never been a patient of mine, was said to suffer from bronchial catarrh in the winter time. He had seen military service. His blood was later examined and found to be Wassermann positive. The aunt, on the mother's side, who brought this case to my notice, had been under treatment by me for functional neurosis of an anxiety type for a period of six months.

NATURE OF ATTACKS.

Immediately after the alarming incident the child was noticed to have an attack of pain and coldness of his hands, feet, and ears. Several attacks had since occurred, the description of a typical one being as follows: When out in the cold the child would become suddenly doubled up with pain, and would cry and have to be taken home at once. The fingers, especially the index-finger of one hand, the toes, and sometimes the whole foot and the pinna of both ears would become black and swollen. On arrival home after such an attack the first specimen of urine passed would be dark coloured, but the colour of the next specimen would be normal. The child would fall asleep and was frequently quite well on awakening, although very nervous and frightened. Such attacks had occurred fortnightly for the past few months, and had increased in severity.

On March 21st, 1930, when I first examined the child, I found him lying on a couch looking very apathetic and atonic. He was pale, but the mucous membranes were not especially anæmic. The legs were wasted and weak, and he could not support his weight for long. There were frontal and parietal bosses, beaded ribs, and well-marked thickenings at the ends of the long bones. The tongue was slightly furred, tonsils slightly enlarged, and teeth very fine and small; no gingivitis was present. There was nothing abnormal in the heart and lungs. The abdomen was somewhat protuberant, and the liver was palpable, but the spleen was not. Reflexes were present and equal, though somewhat exaggerated. No objective changes in sensation could be made out. The optic discs were normal. There was slight œdema on the dorsum of the left foot. A specimen of urine was requested; a day or two later this arrived and was found to be port-wine coloured.

I examined the child at his home on March 24th. On this occasion he looked better than at my previous visit, and indeed got up and began to play with his toys, conversing quite happily with his parents for a few minutes. There was a violet discoloration of the pinna of both ears, and dark coloration of the index-finger of one hand; the feet were normal. The temperature was normal at both visits.

EXAMINATION OF URINE.

The urine was found to contain albumin and to give the guaiacum test for blood. It contained no red cells or casts. The deposit consisted mainly of indefinite brown masses which, when examined with a higher power, were seen to contain masses of pigment. On standing a little, numerous crystals of the coffin-lid variety were deposited (ammonio-magnesium phosphate). I took a specimen to the city laboratory, where Dr. Storer was kind enough to examine it, and he confirmed the absence of casts and red cells. He also demonstrated with the spectroscope the absorption bar characteristic of normal blood.

I was privileged to see a further attack which occurr on April 8th. The fingers and toes were blackish a swollen. There was œdema of the dorsum of both han and feet and the ears were cyanosed. The child on t occasion passed port-wine coloured urine at mid-day (t attack occurred in the afternoon), and also after the atta I have seen the child in two slight attacks since then.

Treatment has been directed towards the maintenan of warmth at all times, the addition of such articles of diet were found to be deficient supplemented by preparatio containing vitamins. Inunctions of mercury have be started.

The case is interesting as illustrating the type Raynaud's disease occurring in children, where t process does not proceed to the stage of gangren The syncopal stage is extremely short and is barel noticeable, the asphyxial stage being the o observed. The profound neurotic history in t family, the influence of cold on all occasions, and t comparative rarity of the disease are interesting. appears to be common in these cases to find a relatio ship with parental syphilis.

RETROPERITONEAL FIBROMA

ARISING FROM THE ANTERIOR COMMON LIGAMENT

By W. H. Ogilvie, M.D., M.Ch. Oxf., F.R.C.S. En
ASSISTANT SURGEON, GUY'S HOSPITAL.

The only interest in the following case, and n only excuse for publishing it after a lapse of eig years, is the rarity of the condition. The presen in a woman of 55 of a large mass in the abdom quite fixed and of almost stony hardness, ma malignant disease the only reasonable diagnos On the other hand, there was no point in the histor symptoms, or preoperative findings to indicate t organ involved. Operation was undertaken pur for purposes of exploration.

A thin married woman, looking more than her age 55 years, came up to the surgical out-patient departm at Guy's Hospital complaining of a throbbing sensation the upper abdomen, which she had noticed for th months. This was the only thing of which she complain There had been no vomiting, loss of weight, or pain, nor h she noticed any lump. All her bodily functions were acti normally.

On examination a prominence was immediately visib occupying the left upper quadrant of the abdomen. T proved on palpation to be a hard solid mass, roughly o in shape, firmly fixed to the posterior abdominal wall. reached inwards to the mid-line, and downwards two inc below the umbilicus, while above it appeared to pass un the costal margin. It formed no prominence in the loin. did not move on respiration, nor could it be moved passive On percussion the splenic dullness appeared to be continu into that of the lump; over the most prominent part th was a band of resonance. The urine was normal. T fæces gave a weak guaiac reaction, but no blood spectru The Wassermann reaction was strongly positive. An X r showed the stomach displaced downwards and outwar by a large mass in the region of the lesser omentum, suggesti a pancreatic cyst.

Laparotomy was performed on May 25th, 1922, throu a left paramedian incision. The stomach, splenic flexu

ıd descending colon were seen to be carried forward on a rge retroperitoneal mass, over the summit of which ran ıe inferior mesenteric vein. The left kidney could be felt ehind the upper pole of the swelling. An incision was made ıtside the descending colon, and the peritoneum and vessels ere displaced inwards as far as the aorta. A smooth, val tumour, 2½ by 4 inches, was thus exposed, surrounded y a distinct capsule and firmly attached to the bodies of ıe second and third lumbar vertebræ. Three of the lumbar teries entered the mass and the aorta was pushed slightly the right. The lumbar arteries were ligatured at their igin and the tumour was separated by the knife from the ıterior common ligament from which it appeared to spring, ıd shelled fairly easily from its capsule. The wound was wn up, a drain being left in the extraperitoneal tissues r 48 hours.

Microscopic section showed the tumour to be a broma with much necrosis. Recovery was uneventful, the patient leaving the hospital perfectly well.

I am indebted to Mr. R. P. Rowlands, whose registrar was at the time, for permission to publish this case.

INEFFECTIVE SWABBING IN DIPHTHERIA EPIDEMICS.

By Guy Bousfield, M.D. Lond.,
DIRECTOR OF THE CAMBERWELL RESEARCH LABORATORIES.

Extensive active immunisation is widely regarded the only effective method of controlling diphtheria. ith this view I have much sympathy, yet the fact ust be faced that even at the present time, in spite many years' experience and contrary teaching, any practitioners still rely on the result of a throat ab examination for the establishment of a diagnosis the commencement of antidiphtheritic treatment. ee The Lancet, Sept. 13th, p. 587.)

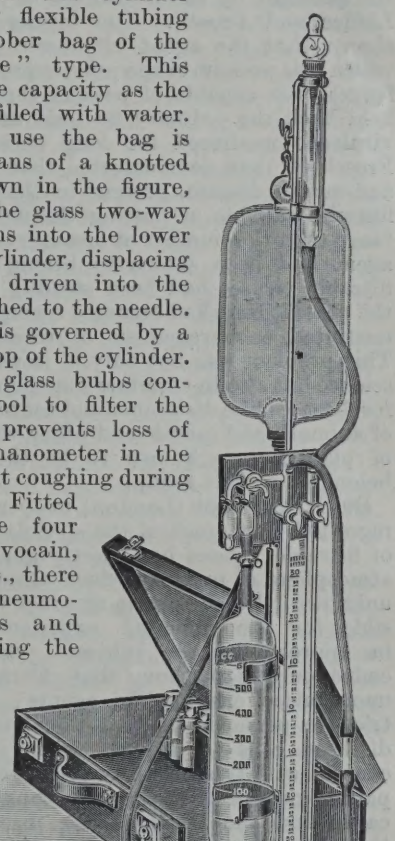
I find that the majority of medical officers who tack an epidemic by means of swabs submit material ken only from the throat. At the most, only a rinkling of nasal swabs, taken from children who ve obvious nasal discharge, is included. I submit at this practice makes the search for carriers actically futile. In examination of many thousands specimens taken during epidemics of diphtheria have identified polar-staining morphological diphria bacilli relatively about ten times as often in sal swabs as in throat swabs. The same may be id of swabs taken from children who must be rtified as free from diphtheria infection before they n be admitted to a convalescent home or other stitution. It is frankly admitted that quite a large oportion of morphological diphtheria bacilli isolated om nasal swabs proves to be non-virulent on animal st; yet exactly the same is true of bacilli found the throats of persons who show no throat lesion. Anatomically the nose tends to empty its secretions rectly to the exterior more than does the throat. uring play and in the absence (or even presence) the pocket handkerchief numerous opportunities r the spread of infection must occur. It is my firm lief that virulent diphtheria bacilli are disseminated ore commonly from nasal than from pharyngeal urces, in many cases by carriers who show no vious symptoms or lesion of nasal diphtheria.

A point of extreme importance is that positive nasal ltures (which may be virulent) are often obtained sily from persons whose throat cultures are contently negative. This fact does not seem to be nerally known. When a search is being made for rriers it is not enough to swab throats alone, and sal swabs which have been inserted into *both* nostrils ould also be submitted from each subject. In addition, any ear discharges must be similarly investigated. If expense does not exclude animal virulence tests, these should be undertaken in each case. When they cannot be done, the only safe procedure is to isolate all positive cases from the main community, whether the source of the bacilli was nasal or pharyngeal, until such time as local treatment has produced a series of negative swabs.

NEW INVENTIONS

ARTIFICIAL PNEUMOTHORAX APPARATUS.

This is a modification of the apparatus described by me nine years ago (The Lancet, 1921, ii., 710). In my former model the air reservoir consisted of a collapsible indiarubber bag. This has now been replaced by a glass cylinder graduated up to 600 c.cm. The lower end of this cylinder communicates by flexible tubing with a stout rubber bag of the "hot-water bottle" type. This bag is of the same capacity as the cylinder, and is filled with water. When ready for use the bag is suspended by means of a knotted silk cord, as shown in the figure, and on turning the glass two-way tap the water runs into the lower end of the glass cylinder, displacing the air, which is driven into the flexible tube attached to the needle. The rate of flow is governed by a screw clip at the top of the cylinder. There are three glass bulbs containing sterile wool to filter the air, and a trap prevents loss of water from the manometer in the event of the patient coughing during the operation. Fitted in the case are four bottles for novocain, iodine solution, &c., there is also room for pneumothorax needles and syringe for injecting the local anæsthetic. The manometer registers intrapleural pressure or pressure at which gas is being injected according to the position of the two-way tap. The apparatus can be used for both injection and withdrawal of measured quantities of gas, and its advantages are that it is easy to handle, it is light and compact, and it can be carried in any position.



The weight of the apparatus, which is made by Messrs. Down Bros., is 7¾ lb. and the outside measurements of the case are 19¼ × 9 × 4½ in.

Geoffrey Marshall, O.B.E., M.D., F.R.C.P.,
Officer i/c Tuberculosis Department, and Assistant Physician, Guy's Hospital.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN WINNIPEG.

(*Continued from p. 607.*)

SECTION OF MEDICINE.

Lord DAWSON presided over the first meeting of this Section and contributed a clinical introduction to a discussion on

Filtrable Viruses and Practical Medicine.

The importance of the subject was obvious, he said, when one recalled that such diseases as measles, mumps, small-pox, encephalitis, and the common cold of temperate climates, and yellow fever, dengue, and sandfly fever of the tropics, were caused by viruses belonging to the filtrable group. The technique given us by Pasteur and Koch, despite developments and improvements, had failed to reveal the ætiological secrets of these diseases, and light was first thrown on the problem by the researches of Ivanowsky and of Löffler and Frosch. The former investigator had shown that the agent of mosaic disease of plants, which was present in the juice expressed from affected leaves, was capable of passing through filters which held back the ordinary bacteria and of retaining its virulence unaltered for long periods. Löffler and Frosch in 1898 demonstrated that the virus of foot-and-mouth disease, present in the vesicle fluid, was likewise capable of passing through bacterial filters. Since then the number of diseases in which the causal agent had been shown to belong to this group of filtrable viruses had been steadily increasing, and at the present time had assumed a magnitude warranting unstinted encouragement of research in this field. This problem was not only of importance to medical science but also to veterinary medicine and agriculture, for diseases like distemper and foot-and-mouth disease of animals, and mosaic and other widespread diseases of plants, were known to be the work of agents belonging to this group.

Dr. S. P. BEDSON (London), in opening the discussion, regretted that much of the speculation on the nature of filtrable viruses had merely gone to heighten the atmosphere of mystery which always surrounded the unknown. In his opinion this fact was largely responsible for the difficulty experienced by clinicians in approaching the subject. Some workers had endeavoured to show that filtrable viruses were unorganised enzyme-like agents; others even had tried to persuade us that they were the product of diseased cells—a product which when brought in contact with fresh healthy cells gave rise to the same pathological process, the virus thus becoming both the cause and the result of the disease. Dr. Bedson thought it would have been more reasonable to approach the question from the standpoint that filtrable viruses were probably akin to bacteria. Adopting such a working hypothesis, the first question to solve was whether these viruses were living. Life was characterised by the ability to multiply, to adapt to alterations in environment, and to assimilate without loss of identity; and since viruses possessed these characters one was entitled to conclude that they were living. One factor more than any other had gone to obscure the relationship of filtrable viruses to the ordinary bacteria, and that was the limitation of visibility with the microscope. Undoubtedly, filtrable viruses were small, some of them truly inframicroscopic, but there was evidence that others —such as the viruses of small-pox, fowl-pox, and psittacosis—could be seen with the microscope. And since there were visible and cultivable bacteria which at the same time were filtrable, it seemed there was good reason for separating filtrable viruses from the ordinary bacteria on the score of size. The difficulty experienced in cultivating filtrable viruses was another reason advanced for their being unlike bacteria. It had been found impossible to grow them apart from living cells, but recent work by Muckenfuss and Rivers suggested that the cells only supplied some diffusible substance necessary for the growth of the virus, so that cultivation in a lifeless medium might eventually be achieved. The more that one learned about filtrable viruses the greater did the resemblance to bacteria become, so much so that the speaker looked forward to the merging of filtrable viruses and bacteria in one large group, inside which, of course, there would be sub-grouping just as there was in the case of bacteria at the present time.

IMMUNITY TO FILTRABLE VIRUSES.

There was a similar tendency, said Dr. Bedson, to differentiate between the immunity produced by filtrable viruses and bacteria. It had become the habit to speak of immunity to filtrable viruses as being solid and lifelong, in contrast to the immunity incited by bacteria which was often weak and fugitive. But such a generalisation was only partially true, for there were virus diseases such as foot-and-mouth disease, herpes, and the common cold, one attack of which conferred little or no immunity, and bacterial diseases like typhoid fever which gave rise to a solid one. Here again, it was impossible to draw a clear dividing line. With filtrable viruses as with bacteria it was possible to produce an active immunity which was associated with the development of specific antibodies, and with these antibodies it was possible to procure a passive immunity and demonstrate those in-vitro immunity reactions which were of such service in the case of bacterial diseases. Active prophylactic immunisation had been practised for some time in the case of small-pox and rabies. In the former disease use was made of the fact that the virus of small-pox, when adapted to the cow, lost its invasive power for human tissues and although this method was good in that it produced a satisfactory immunity, it was not without its dangers. Although opinion varied about the ætiology of post-vaccinal encephalitis there was little doubt that the invasion of the body by the vaccinia virus was directly or indirectly responsible. This had led to the advocacy by the Ministry of Health in England of vaccination by one insertion with minimum trauma and, with a similar object in view, dilution of the lymph had been practised at the London Hospital and in Germany. In the case of rabies attenuated virus was used for immunisation, and it was long thought that this method was not applicable to other filtrable viruses. But recent work by Vallée and his colleagues and the British Foot-and-Mouth Committee had shown that the foot-and-mouth virus still retained its antigenic properties when rendered inactive by means of low concentrations of formalin. The same thing had since been found true for the viruses of distemper, fowl-plague, and yellow fever; and that distemper prophylactic vaccination had been practised in the field with success.

PASSIVE IMMUNITY AND DIAGNOSTIC REACTIONS.

The use of convalescent serum in poliomyelitis was well known in Canada, but perhaps the efficacy of serum in the prophylaxis of measles was not so generally realised. Measles convalescent serum given in suitable doses within the first five days after exposure to infection resulted, as a rule, in complete protection, and given later from the fifth to eighth day modified the attack. The use of serum was

greatest service both in private practice and in itutions and hospitals. Dr. Bedson referred to the k of Gordon, Netter and Urbain, Ciuca and others, wing that both specific flocculation and comple- nt fixation could be demonstrated with filtrable ises and their antisera, and he cited the work of gess, Craigie, and Tulloch, showing the value of flocculation test as an aid to the diagnosis of ll-pox. He mentioned the work done by himself Dr. J. O. W. Bland in connexion with the plement-fixation reaction and cited examples of practical application. In conclusion, he said that ugh some of the problems in this field of research ned almost insuperable, the progress already made uld encourage perseverance. Those who came ore Pasteur must have been faced by problems no difficult.

DISCUSSION.

Dr. N. E. McKINNON (Toronto) confined his remarks he contributions which Canada had made to this stion of filtrable viruses. He spoke of the excellent k done in Winnipeg in connexion with the use of valescent serum in poliomyelitis. During the nt epidemic 66 cases received serum; only 4 hese developed residual paralysis and none died, reas of 54 cases not receiving serum, 34 developed dual paralyses and 6 died. The dosage used was c.cm. intramuscularly. Although the efficacy of sles convalescent serum was known in Canada it not used as extensively as it should be. Between years 1921–29 there were 5000 deaths from sles in Canada; this considerable mortality could oubtedly be materially reduced by the more nsive use of convalescent serum. He referred to apparent freedom from post-vaccinal encephalitis Canada and said that he was inclined to attribute to the method of vaccinating. In Canada the tice was to vaccinate either by a single scratch th in. long or by single puncture; the former hod was preferable, for it gave a higher per- age of takes. In conclusion, he referred to a ll outbreak of psittacosis which had been oughly investigated from the clinical and emiological standpoint.

Dr. D. N. NABARRO (London) spoke of the serum phylaxis of measles. He mentioned the various which had been advocated—Degkwitz's serum, the m prepared against the green streptococcus of nicliff, and human convalescent serum, and said of the three the last was the only satisfactory He gave the results of the use of convalescent m at the Hospital for Sick Children, Great Ormond- et. Serum from adult convalescents alone was loyed, and before being used this was submitted ltration and stringent tests for sterility. Out of 586 cases which had received serum only 21 were protected, and the majority of these developed a ified measles. He considered that the use of valescent serum was of the greatest service in pital practice.

Prof. A. W. M. ELLIS (London) said that the tion of filtrable viruses could be approached from riety of points of view. One thing which struck most forcibly was the evidence pointing to the percentage of carriers of filtrable viruses. He nced herpes in man, certain diseases of plants—of potato in particular—and possibly the encephalo- litis complicating vaccination and many of the ific fevers. The ancients had been wont to speak isease coming from within, but advance in our vledge of the causation of disease had reversed ers, and disease was usually spoken of now as ing from without. The evidence which the study of filtrable virus-diseases was bringing to light required an alteration in our conception of disease.

Dr. BEDSON, in reply, said that he was in entire agreement with all that Dr. McKinnon and Dr. Nabarro had said. He considered that the point raised by Prof. Ellis was a most important and interesting one. Virus carriers did undoubtedly exist, and the evidence available suggested that the balance established between host and virus could be upset by a variety of factors with the result that disease ensued.

Functional Disorders of Colon.

Dr. EDMUND SPRIGGS (Ruthin), in introducing at the second session a discussion on this subject, said that there was no organ about which there had been more difference of opinion. Abandoned by Metchnikoff as a useless relic, stormed by surgeons who removed pieces, or, when most merciful, stitched it up, laved with many waters by physicians and dosed by the public, it had been, and was, a battlefield, the Flanders of medicine. It was, indeed, fortunate that the large bowel, though easily injured by wrong habits or treatment, had great power of recovery. For knowledge of the diseases of the colon the profession owed much to Sir William Hale-White, whose papers from 1888 on classified these disorders, with clinical descriptions that have not been surpassed. In 4000 cases under Dr. Spriggs's care a note concerning the colon was made in 2086 by Dr. Mary Watson. In many the only mention was of delay. In 1543 some other major or minor abnormality was noted from the symptoms, signs, motions, or X ray examinations. The distribution of the lesions or disorders was as follows: obstruction, 19; parasites, 20; ulcerative colitis and colitis gravis, 29; dysenteries, 29; growths, 32; loops and redundancies, 45; colectomy, colostomy, and colopexy, 51; adhesions, largely post-operative, 85; mucous and mucomembranous colitis, 164; coloptosis, 202; diverticulosis and diverticulitis, 297; disorders of tone and segmentation, 570. The last group included 198 with excessive tone and spasm, and 84 cases of irritable colon with prominent clinical symptoms but little or no mucus.

The conditions classed by Dr. Spriggs as functional were colonic delay or constipation, irritable colon including nervous diarrhœa, spastic colon, mucous colitis or catarrh of the colon, and mucomembranous colitis. The word colitis, he remarked, is not strictly correct, but is used. In 141 consecutive cases of coloptosis, in 27 per cent. there was great delay, in 55 the rate of passage of the barium meal was normal, and in 35 others the delay was moderate only. Hence, in more than half, retardation was inconsiderable. It did not matter where the colon lay so long as it passed on its contents normally. Symptoms arose from dropping per se in severe cases only. Among the ætiological factors were mentioned infections, parasites, exposure and other injuries, and the two main causes—neurosis and constipation—were discussed. Dr. Spriggs suggested that the usual treatment for constipation—namely, irritating aperients—taken over long years was as potent and frequent a cause of colitic disorder as constipation itself. This was confirmed by the good result of withdrawal and by an analysis (by R. Picton-Davies) of 1000 cases of radiological delay under the speaker's care. Of these, 236 were unaware of constipation, and 764 complained of it. Of the latter, 670 were taking aperients, 436 every day. In 242 cases of mucous colitis and irritable colon, in roughly half there was or had been some other lesion or suspected lesion of the alimentary tract, the most prominent

being appendicitis, disease of the gall-bladder, and ulcers of stomach or duodenum. These cases should be observed carefully, and the practice of operating first and investigating afterwards avoided.

Under the heading of pathology, the view was put forward that sluggishness of the bowel leads to venous stasis, with diminished absorption of gas, and that interference with motility may be a cause of flatulence more than the usually alleged fermentation. Redundant loops were mentioned, and the *bacteriology* reviewed. Experimental grounds for indiscriminate vaccines were, said Dr. Spriggs, lacking. The estimate of what value they might have rested on a clinical and not on a scientific basis. Statistics of cultures were quoted, showing that streptococci were less common in constipated, and more so in loose motions. From the results of 2000 cultures it appeared that in the present state of our knowledge, repeated culture of the motions in these disorders, after the preliminary diagnostic examination for organisms known to be pathogenic, was not worth the time and labour involved.

The chief symptoms were: abdominal pain or discomfort, 80 per cent.; poor appetite; nausea, 24 per cent.; vomiting, 16 per cent. Constipation was usual and many complaining of diarrhœa showed with X rays delay in the bowel. The incidence was also given of weariness, depression, headache, malaise, palpitation, heart pains, shivering and cold hands and feet. Among signs it was mentioned that in 111 cases the gastric juice was superacid in 41 per cent.; subacid in 23 per cent.; achlorhydric in 2 per cent. As regards colonic delay, proved radiologically in the 1000 cases quoted, the delay was in the whole colon in half, and in the sigmoid or rectum, or both, in one-third. Cæcal delay alone was rare (1 per cent.), and often means local inflammation; 289 complained of headache and 181 were depressed or neurasthenic. Stress was laid upon inspection of the motions.

The main rules of treatment were these: to allay anxiety, to abolish laxatives and purges, to give a suitable diet, and to regulate rest and exercise. In severe cases it might be necessary to remove the patient for a long period from surroundings in which the derangement arose. The patient was often convinced that it was harmful for material to lie in the colon for more than 48 hours; that if an action did not take place in the morning an aperient should be taken that evening, that the large semi-fluid motions produced by aperients, to yield which a great part of the colon was emptied, were beneficial; that an ordinary formed motion due to the emptying of the lower sigmoid was not enough; that abdominal disorder and loss of vitality were lessened by the use of aperients. In the main, said Dr. Spriggs, these opinions were wrong and he gave reasons for thinking so. Diet suitable for different cases varied from a bland one in severe cases (used in 42 per cent. of this series) to a rougher diet in milder ones. The use of paraffin, massage, baths, intestinal douches, exercise, electrical treatments, rest (including mental rest), and other measures was discussed. Drugs such as belladonna, hyoscyamus, intestinal antiseptics, castor oil and salines, were mentioned, also special measures for severe mucous colitis, spastic cases, and nervous diarrhœa.

Experience of surgical operations for functional disorders of the colon was, said Dr. Spriggs, unconvincing. No operation had been or would be devised which would make a man out of training fit to run a race. In these patients the bowel was out of training and surgery as a means of restoring its powers is usually futile. The results of the treatment of 208 cases were quoted. 34 per cent. were treated in bed at first, 64 per cent. with douches, 11 per cent. wh castor oil. In 90 per cent. much benefit was obtai from a course averaging 6·7 weeks in length. If t be given relief is nearly always possible and cur frequent. Each patient should follow detailed instr tions under the care of his doctor on returning ho

"These diseases do not kill," the speaker conclud "but they cause weakness and misery. If we educate doctors as a profession and the public regard to the hygiene of the colon, a great addit will have been made to human health and happine

DISCUSSION.

Dr. E. E. CLEAVER (Toronto) gave an account modern work upon the structure and functions of colon, its movements, control by nerves, and, shown by Hurst, its lack of sensation except at lower end. Digestion, absorption, and secretion the lower bowel were assessed, the main funct being that of a reservoir. Much prevalent deran ment could be avoided if the diagnosis were made the doctor and not by the patient.

Dr. HUGH BARBER (Derby) said these disord could often be cut short. Although predisposed by a sensitive nervous system, they occurred at periphery, and were only partially controlled by central nervous system. Thus, in nervous diarrh belladonna with bromide would quiet the irrita colon, and the patient then finds that faith wo play its part, the peripheral control teaching a les to the higher centres. Fatigue was a cause—e.g., a schoolmaster at the end of term. Mucus was due too much purgation as well as to hard fæces. T intractable chronic states would seldom occur if doctor had had a chance to advise or control at beginning.

Prof. THOMAS MCCRAE (Philadelphia) put nerv predisposition first in his list of causes, and constipat with the use of laxatives second; later, the probl was a mixed one. He spoke of the harmful characte some popular health articles, and of advertiseme of aperients and food fads in the lay and medi press. The word "autointoxication" ought, said, to be cut out of the terminology. Orga states must be excluded and especially diverticulo The prostate should be thought of also in m Allergy in this class of disorder might be striking, examples were uncommon. He agreed with Spriggs's conclusions about aperients, viscerpto bacteriology, and the importance of inspection of whole stool, not a sample. Some needed a spec diet, but in others the best therapy was to tell them forget both diet and colon. He used irrigation, less than formerly. The value of surgery in th complaints was illustrated by the reply of a scho boy to a question about Caligula. Knowing nothi he wrote, "the less said about Caligula the bette and received full marks.

Prof. T. GILLMAN MOORHEAD (Dublin) said t the function of the colon was of importance, but its position. It was undesirable to make a diagno to the patient of dropped colon, as it was hard aft wards to get the idea of abnormality out of his or head. Abdominal belts should not be used unl the abdomen was pendulous. He agreed with t strictures on the abuse of aperients, but they co be taken in moderation for years by those who w not nervous without harm.

Prof. WILLIAM WRIGHT (London) said that refl mucous colitis was especially likely to be caused disease in structures, such as the hip and the prosta which were supplied with nerves from the same p of the cord as the sigmoid. The great variations

e anatomy of the lower colon must not be forgotten. ie rectal valves might form an almost complete aphragm, or the ampulla be large, causing lodging fæces with mucous discharge.

Lord DAWSON OF PENN agreed with the retention the term "colitis" for these cases. Labels were eded and the doctor should not mistake them for e things labelled. The tendency to an unduly sponsive abdomen was inborn and was associated th low blood pressure. The high tension patient ok the strain in other ways. He was satisfied that tulence was due to disturbance in motility more an to fermentation; in some the distension came on idly from mental causes. Many of those people re attempting more than they could do, trying to t a quart into a pint pot. Attacks in some were ught on by taking food too soon after fatigue and posure, and could be avoided by resting and rming the extremities before the meal, which uld then be simple, sometimes just bread and milk. herwise diet should not be strict because such ail raises the abdominal consciousness. Exercise needed, but many overdo it at week-ends. Repose body and mind for half a day or a day a week s recommended. He had the impression that pancreatic and duodenal preparations were sometimes value, and, for the overstressed, bromide and alin. He endorsed the necessity of understanding patient's outlook, and allaying hidden fears and interpretations. This was best done by incidental versation, plain reasons being given for the advice dered.

Dr. EMMET KEATING (Chicago) said it was of cial importance to avoid palatable aperients. He d Epsom salts which, on account of the unpleasant te, the patient would be less likely to take to excess.

REPLY.

Dr. SPRIGGS said that most of his patients in this ies had a low blood pressure. The average of the cases was 128/77, and the average age 43. Dr. rst's account of the gastrocolic reflex had been firmed by Mr. Marxer. He was interested in f. Wright's reference to the nervous supply of sigmoid for left sciatica, and herpes of the lumbar sacral nerves were, he had found, unduly frequent h lesions of the sigmoid, especially diverticulosis. e preparations were sometimes useful. Purges, if ded, should be prescribed by the doctor like other licines. If a belt was to be used for a dropped mach or colon, its efficiency should be tested by ening with the belt on and off, with some barium he stomach or colon, or both.

Sea Sickness.

Dr. T. GWYNNE MAITLAND (Liverpool) described ong and interesting series of observations by self, Group-Captain Martin Flack, R.A.F.M.S., Dr. J. R. Marrack. He discussed the kinds of vement that cause vestibular nausea, referring to pitch, roll, yaw and ascent of a ship at sea; also lane and train sickness. Quick movements, such rotting on horseback, do not cause these symptoms. points were illustrated by models of the internal and by a revolving chair. Although the complaint not its former terrors, there was no panacea; and e seasoned sailors never became immune. The s that in many equilibrium soon adjusted itself that the average storm abates in two or three days e sometimes forgotten when the value of remedies assessed. They had tested, with controls on the e ship, over 70 proprietary remedies. None of se was a certain preventive or cure.

SECTION OF SURGERY.

ON the second day of the meeting this Section held a symposium on the uses of

Radium in Surgery.

With one exception the contributors were British workers, and the discussion as a whole gave an adequate presentation of the recent work on radium in this country. It was the more to be regretted, therefore, that no one was present who could give an account of radium treatment of cancer of the breast, such as has been carried out during recent years at St. Bartholomew's Hospital.

CARCINOMA OF THE RECTUM.

The discussion was opened by Sir CHARLES GORDON-WATSON (London), who reported his recent work on the treatment of carcinoma of the rectum. One of the great advantages offered by radium was the possibility of curing the disease without recourse to the colostomy that was inevitable during some stage of treatment when present-day surgical methods were employed. The problem of radium versus surgery, however, was complicated by the recent work of Cuthbert Dukes on the spread of cancer of the rectum. This work suggested that it was not necessary to excise the rectum completely in order to obtain thorough eradication of an early carcinoma which had not penetrated the wall of the rectum. If this work was substantiated it might be possible in the future to obtain a cure by more limited operations than were at present used, and without recourse to permanent colostomy. There was no doubt, Sir Charles said, that an early growth of the rectum could be destroyed by radium, without colostomy and without disturbance of the function of the rectum, but no observations were as yet available on a five-year basis.

He had, he said, treated 121 cases of carcinoma of the rectum with radium. Small growths could be destroyed with little or no resulting deformity of the rectum. The adenocarcinomas varied greatly in their radio-sensitivity, and it was desirable that attempts should be made to grade tumours histologically, and to correlate such findings with the radio-sensitivity of the tumour. Unexpected failures had been encountered in the radiation of early growths, but fortunately these failures could be made good by surgery. Rapidly growing adenocarcinomas in young people were more radio-sensitive than slow-growing tumours in elderly patients. In these the dose of radium required to secure complete retrogression of the tumour was very near the margin of tolerance of healthy tissues, and consequently radium burns were difficult to avoid. β-radiation should be reduced to a minimum. The speaker had used filtrations of 0·5 or 0·6 mm. of platinum, but in the future he intended to increase this filtration to 0·8 mm. He left the needles in the tumour for ten days. Radium was preferred to radon because of its uniform intensity of irradiation. For tumours of the perineal portion of the rectum, the results so far obtained were too uncertain to justify the preference of radium to surgery in the operable type of case. Carcinomas of the rectum that lay above the peritoneal reflexion were treated by radium when the tumour was fixed or when, in operable tumours, the age or state of health of the patient forbade an abdominal perineal excision. Transperitoneal radiation was essential in these cases, and it was a more risky procedure than perineal radiation, for there was danger of infection and consequent paralytic ileus or general peritonitis. Radon seeds were less dangerous than radium needles inside the peritoneal cavity,

but so far the end-results when radon was used were not encouraging. Radon or radium was also used inside the peritoneum for barrage treatment of the mesenteric glands. The speaker mentioned one excellent result in which an inoperable tumour fixed both to the bladder and to the sacrum had been treated by radium needles, and the patient was alive and well, with a normally acting rectum, three years after treatment. In other cases great symptomatic improvement had followed the use of radium.

Sir Charles then discussed squamous-celled carcinoma of the anus. This tumour responded much better than any of the others so far considered, and in early cases, immediate initial cure could be obtained by radium. The consequent avoidance of colostomy rendered this method preferable to surgery. The various methods and routes by which radium could be applied to carcinomas of the rectum were then considered, and the speaker closed with a plea for team-work between the physician, surgeon, pathologist, biochemist, and physicist to enable the radium worker to conduct his practice on a scientific rather than an empiric basis. He also showed a film illustrating implantation of radium needles into a rectal carcinoma by the perineal route.

ORAL CARCINOMA.

Radium treatment of carcinoma of the mouth and tongue was the subject of the next three papers by Mr. STANFORD CADE (London), Dr. DOUGLAS QUICK (New York), and Dr. G. E. BIRKETT (Manchester), whose paper was read by Prof. A. H. BURGESS. In many aspects there was remarkably close agreement between these three workers, and as a result there emerged a fairly authoritative declaration of the methods of treatment of buccal carcinoma. For treatment of the primary carcinoma all were agreed on the advantages of radiation over surgery, but whereas Mr. Cade and Dr. Birkett favoured radium needles, Dr Quick preferred radon seeds. In the opinion of the first two speakers it was difficult with seeds to obtain a uniform intensity of radiation, not only because the intensity of the radiation rapidly diminished within a period of four days, but also because the small seeds could not be so accurately placed as the larger needles. Carcinoma of the posterior part of the tongue, especially in or near the vallecula, and the lingual tonsil, was much more radio-sensitive than the more differentiated carcinoma of the anterior part of the tongue, but it was prone to give rise to early metastases. For the treatment of metastases of the neck that were operable, all the speakers favoured free surgical excision on the lines laid down by Crile. They stressed the importance of very radical removal and urged that the operation should only be carried out by those who were especially trained and practised in its performance. An incomplete dissection of the neck was worse than useless. When there were large inoperable metastases the glands should be actively treated by radium needles in large doses and the balance of opinion favoured open operation as the method by which this treatment should be carried out. For early cases in which no palpable metastases could be found there was sharp divergence of opinion as to the treatment of the neck. Dr. Birkett advocated a waiting policy, provided the patient reported for examination once a month. Mr. Cade and Dr. Quick, on the other hand, believed that the neck should never go untreated. Mr. Cade advocated needling of the neck by the closed method, or as an alternative external treatment by means of a radium collar. Dr. Quick employed heavily filtered high voltage X radiation, and more recently a four-grain radiu element pack. Speaking of the radium bomb at t Westminster Hospital, Mr. Cade felt that it was t early to form a judgment of its value, but he did f that it was not an economic method of using radiu for the same amount of radium used in the form needles would treat ten patients where only one co be treated by the bomb. Dr. Quick stressed t importance of cleaning the mouth before treatment the neoplasm was begun, and as a preliminary irradiation of the primary tumour, he recommend external irradiation of the neck and the site of t primary growth for a period of two weeks. T results of treatment reported by the speakers cann be adequately reported in abstract, but the impressi formed was that radium treatment gave results th were definitely better than those of surgery alo especially when it was remembered that healing w attained with no impairment of speaking, eating, a drinking. Dr. Birkett made a strong plea for t concentration of radium treatment at large centres.

CARCINOMA OF THE BLADDER.

Mr. FRANK KIDD (London) reported the resu of treatment of 32 cases of carcinoma of the bladd by radon seeds after preparatory diathermy. some cases the treatment was administered by op operation, in others by the cystoscope. Sixte cases were alive and well for periods up to eight yea and two others were still living, but showed eviden of recurrence. In some of the fatal cases the u of radon had appeared to accelerate the course of t disease. It was sometimes difficult to estima accurately the extent of the tumour, even at op operation, and the results were still not predicta with any certainty. There had been some ve encouraging results, and further work along the lines was indicated.

CENTRAL NERVOUS SYSTEM.

Mr. HUGH CAIRNS (London) reported on wo done during the last three years in the use of radiu in the central nervous system. For a variety reasons it was highly desirable that radium shou be given an extensive trial in the treatment malignant intracranial tumours. These tumours we unlike most of those hitherto treated by this metho as they did not give rise to systemic metastas The greatest problem of the neuro-surgeon in doi radical extirpations of infiltrating intracranial tumou was to avoid maiming the patient by removi healthy nervous tissue. If radium could be sho to have a selective action on malignant gliomas, great advance would be achieved in the treatment these tumours. Results so far observed gave eviden that in certain types of glioma radium had a destructi effect on the tumour. It was too early as yet pronounce on the results of radium treatment in th field. In assessing the results it was necessary distinguish clearly between symptomatic improv ment that followed relief of hydrocephalus and th which was actually due to destruction of tumo tissue. The methods of using radium and radon intracranial tumours were briefly described.

GENITO-URINARY TRACT.

Mr. CLIFFORD MORSON (London) discussed th radium treatment of malignant diseases of the genit urinary tract. By far the most favourable of these neoplasms was carcinoma of the penis. He h treated seven cases of this disease with radium, a had had six successful results. The one failure h been due to pyogenic infection.

Throughout the meeting emphasis was laid on the view that radium should not be regarded as a panacea for cancer. The whole discussion was conducted in a critical spirit. It was evident that much more work was necessary in all fields before the position of radium in treatment could be properly assessed, but the general attitude was one of cautious optimism.

The Sympathetic Nervous System.

On their final day the Surgical Section considered various aspects of the physiology and the surgery of the sympathetic nervous system. Dr. W. J. MAYO (Rochester, Minnesota) opened the discussion by giving an historical account of the discovery of the anatomy and physiology of the sympathetic ganglia and rami, mentioning the contributions of Winslow, Pourfour du Petit, Haller, Remak, Müller, Claude Bernard, and Gaskell and the Cambridge school. He pointed out that the surgical approach to the sympathetic involved the wider problem of the relation of this system to the endocrine glands. Dr. Mayo was unwilling to admit that removal of a single adrenal caused any permanent disturbance in the physiology of the organism, and he therefore questioned the wisdom of such a procedure in patients suffering from high blood pressure. In closing, he referred to the effect of ramisection on conditions such as arthritis, Raynaud's disease, and the Buerger syndrome, and asked whether certain kidney disturbances and coronary disease may not be an end-result of a similar vasospastic process, and whether early sympathectomy might not prevent the onset of angina pectoris and allied disturbances.

THERAPEUTIC RAMISECTION.

Dr. N. D. ROYLE (Sydney, Australia) followed with a paper entitled the Clinical Results following the Operation of Sympathetic Ramisection, in which he stated that he had performed the operation 100 times, with a mortality-rate of 0·5 per cent., —i.e., three deaths. The operation was introduced by him originally in October, 1923, for the treatment of spastic paralysis, and, excluding extrapyramidal conditions, 70 per cent. of the patients so treated have, he said, been distinctly benefited. A large proportion of them have been followed carefully, and end-results were summarised. More recently Dr. Royle had used the operation experimentally for treatment of the following conditions: parkinsonian rigidity (results poor); Hirschsprung's disease (results excellent in all cases); sarcoma of the femur (relief of pain); Raynaud's and Buerger's diseases (results gratifying, better, however, in the former condition); writer's cramp (one case, relief); poliomyelitis (results poor); condition simulating tic douloureux (one case); retinitis pigmentosa (five cases; recovery of vision following extirpation of thoracic sympathetic). The most important new development relates to Dr. Royle's discovery that retinitis pigmentosa responds to sympathectomy to a degree that caused the recovery of 20/30 vision in one patient whose visual acuity had previously been reduced to shadow perception. Royle still enthusiastically favours the operation of ramisection in cases of spastic paralysis.

PHYSIOLOGICAL PRINCIPLES.

Dr. J. F. FULTON (Oxford), who discussed the physiological basis of the surgery of the sympathetic system, described first the relation of this system to the general physiology of the organism, mentioning Claude Bernard's prediction that regulation of the internal activities of the animal body is carried out by the nervous system, and alluding to the recent discovery that the centres of the autonomic system lie in the hypothalamus (J. Beattie, G. R. Brow, and C. N. H. Long [1]). In discussing the mechanism of postural responses, Dr. Fulton pointed out that the stretch reflex, which is at the basis of posture, is abolished by sectioning of either the posterior or the anterior roots, but not by sympathectomy, although the transient diminution in rigidity occurring in spastic cases after ramisection suggests that the operation may cause an increase in threshold for eliciting the stretch reflex. From the physiological point of view the justification for the employment of ramisection in cases of hypertonia is still an open question. The operation of periarterial sympathectomy is without anatomical or physiological foundation —i.e., there are no long vasoconstrictor fibres passing distally in the larger arteries. The operation may, however, be useful for the relief of intractable pain. Apart from certain visceral conditions, such as Hirschsprung's disease, the only clear-cut indication for sympathectomy is ischæmia. Any pathological process in which healing would be greatly accelerated by an increased blood-supply offers an indication for ramisection, especially if the morbid process threaten the existence of an extremity. Since collateral circulation in a limb is established more readily after ramisection than with vasoconstrictors intact, an extremity in gangrene from thrombosis should not be amputated without first giving it the benefit of ramisection. It was emphasised that conditions improved by sympathectomy are not due necessarily to hyperactivity of the sympathetic.

SUCCESSFUL OPERATIONS.

Dr. J. R. LEARMONTH (Rochester, Minnesota) emphasised that the action of both parasympathetic and sympathetic nerves upon the bowel and bladder should be regarded as a means of harmonising an important physiological necessity—the disposal of the waste products of the body. Operations upon the sympathetic nerves of the bowel are indicated in cases of nervous imbalance, such as Hirschsprung's disease, and constipation due to dulling of the defæcation reflex. He described a new operation by which the whole sympathetic nerve-supply to the lower colon, the rectum, and the internal anal sphincter could be interrupted, with preservation of the vasomotor nerves to the limbs. In the case of the bladder, he described two cases in which defective micturition, due to lesions affecting the parasympathetic pathway, had been rectified by division of the sympathetic nerves to the bladder, and advanced the hypothesis that these nerves might mediate an inhibitory action on the musculature of the human bladder. He also described cases of vesical dysfunction which had been benefited by removal of agents compressing the dural sac under a lumbar or sacral spina bifida occulta. The operation of total denervation of the bladder was also referred to.

Dr. R. B. WADE (Sydney, Australia) gave a report of progress concerning the treatment of Hirschsprung's disease. He has now carried out left-sided lumbar ramisections for this condition in 14 cases, and has had striking improvement in all but one instance, with the establishment of regular bowel movements and normal control of the anal sphincter. The unsuccessful case responded temporarily, however, when the rami on the right side also were sectioned. The unilateral operation has been employed in many cases of chronic constipation with satisfying results. Dr. Wade is of the opinion that Hirschsprung's disease is due chiefly to over-action of the O'Beirne sphincter.

[1] Proc. Roy. Soc., B., 1930, cvi., 253.

VASCULAR CHANGES IN EPILEPSY.

Prof. W. G. PENFIELD (McGill) read a paper on Vascular Changes Observed in the Brain during Epileptiform Seizures. He mentioned at the outset that he had been able to demonstrate small medullated nerve-fibres supplying a large proportion of the cerebral blood-vessels; he then described three cases of epilepsy in which, during exposure of the brain under local anæsthesia, sharply circumscribed areas of anæmia appeared at several points in and about the motor area in the course of several carefully studied focal seizures. In the second case, one of the recorded seizures consisted merely of clonic twitching of the eyelids and turning of the eyes to the right, and the seizure was associated with an isolated area of chalky pallor in an area corresponding to the frontal eye field. In some circumstances the larger cerebral arteries were seen at several points to constrict sharply, giving a beaded appearance to the whole vessel. Dr. Penfield concludes that since stimulation of the sympathetic never causes such extreme vasomotor activity, the cerebral vessels must receive some innervation other than the sympathetic, and therefore that surgical extirpation of the sympathetic in epilepsy is of dubious value.

PERIPHERAL VASCULAR DISEASES.

Dr. A. W. ADSON (Rochester, Minnesota), who dealt with the Indications for, and the Therapeutic Value of, Sympathetic Ganglionectomy and Trunk Resection in the Treatment of Peripheral Vascular Diseases, mentioned the two existing theories concerning the origin of Raynaud's disease; one, upheld by Lewis, who maintains that the vascular spasm is due to a purely local condition in the tissues affected, while Adson and others contend that the disease results from hyperactivity of vasoconstrictor reflexes, and that the fault, therefore, lies in the central nervous system. Dr. Adson pointed out that in his cases, after complete removal of the vaso-constrictors supplying the lower limb, it is impossible to evoke vasomotor spasm, however intense the stimulus. The occasional persistence of spasm in the upper extremities was attributed to failure to remove all fibres. The more favourable results from the radical procedure recently introduced for the upper extremity supports this inference. At the Mayo Clinic the suitability of a case for operation is determined by a "vasomotor index"—i.e., the ratio of the rise of temperature in the extremities to that in the mouth in fever produced by injection of typhoid vaccine. Adson also has proved that retinal arteries dilate after thoracocervical ramisection. In concluding, Dr. Adson showed his first case of Raynaud's disease operated on five years ago, which had remained free of symptoms during that period (lower extremities), and also a case of Buerger's disease in which the morbid process had been successfully arrested in the upper extremities two years previously.

At the end of the discussion, Lord MOYNIHAN read in title a paper by S. H. HARRIS and R. G. S. HARRIS, of the Urological Department of the Lewisham Hospital, Sydney, on Renal Sympatheticotonus and Renal Sympathectomy. The operation which they describe was introduced in the hope of relieving certain obscure cases of persistent renal pain. The paper detailed the nerve-supply of the kidney, the operative technique for denervation of the kidney, and the indications for the new procedure. Pain associated with delayed emptying of the renal calices and pelvis, together with dilatation of the pelvis, constitute the chief positive signs. The writers propose to consider at a later time the relation this operation to nephritis and essential hæmaturi

DISCUSSION.

In the discussion which followed, Dr. ROBERTSO (Toronto) described a case of spastic paralys operated on in his clinic by Royle three years ago, i which the result was distinctly favourable, and h remained so. He also mentioned several cases arthritis and of Hirschsprung's disease, which hav been successfully treated by ramisection.

Dr. FLOTHOW (Seattle) said that he had see Dr. Royle's cases in Australia, and could confirm h claims. He then described a case in which som months after lumbar ramisection a cervical ganglio ectomy was performed, and during the gener hyperthermia (108°) which followed operation th lower extremity, whose lumbar sympathetic chai had been removed, showed evidence of extrem vasoconstriction.

Lord MOYNIHAN said that surgery was now enterin an era which might aptly be termed an era of physio logical repair. The divorce of physiology and anatom that supervened at the close of the career of Sharpe had been unfortunate, and its ill-effects had persiste up to the present time. Lord Moynihan, howeve seemed to discern the restoring hand of the surgeo The synthetic action of surgeons begun by Dr. Royl was bringing physiology and anatomy together agai not by means of animal physiology, but by means o human physiology. The inaugural symptoms o disease should be studied by those who were familia with normal physiology rather than with the patholog of the post-mortem room.

SECTION OF MENTAL DISEASES AND NEUROLOGY.

THIS Section met under the presidency o Sir FARQUHAR BUZZARD (Oxford), and its firs discussion was devoted to abnormal mental an nervous conditions associated with

The Menopause.

Dr. GEORGE RIDDOCH (London) began by definin the involutional period as that phase of life durin which the reproductive functions diminish and becom finally extinct. He pointed out that men, as wel as women, experienced this period of involution although usually to a less degree. In women th climacteric period was a general reaction to ovaria deprivation. Much was still unknown about th nature of the reaction, but it was clear that th primary response was due to other endocrine glands more especially those in most intimate functiona relationship with the ovaries. Of these the supra-renals, pituitary and, in particular, the thyroid, played a leading part. Involved in the reaction was the nervous system, through its autonomic or vegeta-tive portion, which was delicately influenced by, and in turn influenced, the so-called ductless glands, especially the thyroid and suprarenals. The reaction might be towards an increased or diminished activity, which was not uniform but in general varied with each gland, and also with individual constitution. Many of the symptoms of the climacteric were due to this glandular imbalance.

Maranon, said Dr. Riddoch, had insisted on the recognition of three stages in the clinical picture of the climacteric: (1) premenopausal, (2) menopausal, and (3) post-menopausal. Among the more usual symptoms and signs the most noteworthy were

motional instability, vasomotor reactions, and change
n sexual feelings. The tendency to hot flushes
as important not only on account of the physical
iscomfort to which they gave rise, but even more
ecause they aggravated the tendency to emotional
nstability.

Mental complications of the climacteric depended:
1) on constitution and temperament; (2) on the
motional and physical background; and (3) on
reconceived notions about the climacteric. They
ell into two groups—the psychoneuroses and the
sychoses. Melancholia was, he thought, the com-
onest expression of a psychosis and the picture of
nvolutional melancholia was distinct from the
anic-depressive syndrome. Other varieties of
ental disorder mentioned included chronic paranoid
sychosis, confusional insanities, and mental disorder
ith or without polyneuritis or some other organic
isease.

As regards prognosis, the speaker held that in the
sychoneuroses the outlook was largely dependent
pon how far the environmental incompatibilities
ould be overcome, and the attitude of the woman
ould be adjusted to the disappearance of youth and
productive functions. In the pyschoses the prospect
f recovery depended upon several factors, most
erhaps on the reaction type of the illness, but also
pon the physical health and general management and
are. Whatever the mental illness might be, the
rognosis was worse if it is complicated by cerebral
terio-sclerosis.

Treatment was discussed under the headings of
rophylaxis, glandular therapy, and psychotherapy.
n regard to prophylaxis, Dr. Riddoch thought that
good deal could be done for women who were
pproaching the climacteric. They should be
rotected from anxiety and their general bodily
ygiene should be kept at as high a level as possible.
hey should be reassured and reminded that "the
ange" was a normal process safely endured by the
ajority. He had obtained little success with the
arious glandular preparations. He attributed his
oor results partly to the lack of standardisation
f these products, and partly to the small dosage
ten advised by the manufacturers. Thyroid extract
ould be carefully used where there were signs of
yxœdema. Dr. Riddoch strongly opposed deep
ental analysis, by which attempts were made to
elve into unconscious processes. He thought this
ode of treatment not only unwarranted but actually
angerous. He advocated special homes for the care
f the psychotic.

STATISTICAL EVIDENCE.

Dr. C. B. FARRAR (Toronto) showed charts based
n admission to the Toronto Psychopathic Hospital,
etween the ages of 40 and 55 between June, 1928,
nd June, 1930. In this group there were 739
omen and 632 men, and the study seemed to justify
he conclusion that abnormal mental reactions during
he climacteric are more common in single than in
arried women; and that the maximum incidence
omes well before the normal climacteric period.
n males the peak is reached at a slightly later age.
r. Farrar thought there was always more than one
ausal factor operating. The more important of
hese he listed as follows: (*a*) exaggeration of
onstitutional traits, 47·5 per cent.; (*b*) physiology
f the menopause, 44·9 per cent.; (*c*) habitual
enstrual variation, 9·8 per cent.; (*d*) early involu-
onal changes, 8·1 per cent.; (*e*) psychology of
enopause, 1·6 per cent.; (*f*) factors independent
f life epoch, 26·2 per cent. Since over half of his cases were in good physical health he was not inclined to believe that physical disabilities were a potent factor in the production of abnormal mental reactions associated with the climacterium. He could draw no conclusions from his series regarding the occurrence of various types of physique. Pyknic and asthenic types were in the minority; 75 per cent. of his cases were discharged to their homes either completely recovered or greatly improved; 10·2 per cent. died in hospital and 15·2 per cent. were still in hospital. The length of hospitalisation varied from four and a half months to one and a half years.

CLINICAL VIEWS.

Dr. C. A. BARAGER (Brandon) maintained that the physical or structural changes of the menopause had not been sufficiently emphasised. Abnormal mental states are more common during the involutional period than at any other time. In his experience these states had been more common amongst women than men. He felt that recovery was to be expected. Early diagnosis from manic-depressive psychosis was often difficult or impossible. Schizophrenic reactions might also simulate the menopausal disorders. Prognostic results as seen by him were not as good as indicated by Dr. Farrar. Psychological changes, such as a change of outlook on life, played a great part in the production of these mental changes. A complete readjustment was necessary to everyone at this time of life.

Dr. J. G. MCKAY (Vancouver) believed that the outcome would be better if these cases were seen by the psychiatrist early. Differentiation of psychoneurosis from actual psychosis was often difficult, but each case should be treated according to its peculiar features rather than according to an artificial or arbitrary classification.

Dr. R. G. ARMOUR (Toronto) felt that the increased numbers of patients now taking advantage of mental hospital care was a good thing. The course of the illness in hospital patients was apt to be shorter than in those treated at home. He advocated the therapeutic use of ergotine and said he had had encouraging results with deep X ray therapy when this was begun early. This, however, involved early and accurate diagnosis. He admitted to poor results with glandular preparations.

Colonel HAMILTON, F.M.S., asked if the fact of a woman having borne children was likely to influence the severity and course of the condition. His impression was that women who had borne children got off more lightly than those who had not. He had used ichthyol therapeutically with good results. He was ignorant, however, of the rationale of its use, and expressed a desire to be informed.

Dr. RIDDOCH, in his reply, said he thought there was no essential difference between the so-called normal mental reaction of the climacterium and the psychoses, and that behind it all there was a physiological change. He said he spoke as one who saw early cases, in which the prognosis was usually good. The common factor in all forms of treatment was the influence of the doctor on his patient.

Dr. FARRAR closed the discussion. He said he felt sure that suicide was a danger in the psychoneurotic as well as the psychotic; and as the differentiation of severe psychoneurosis from psychosis was often difficult, the patient should be treated with the idea of suicide prevention in mind, even though it was not felt that an actual psychosis was present.

REVIEWS AND NOTICES OF BOOKS

Surgical Diagnosis.

By American Authors. Edited by EVARTS AMBROSE GRAHAM, A.B., M.D., Bixby Professor of Surgery, School of Medicine, Washington University. London: W. B. Saunders Co., Ltd. 1930. Vol. III. and Index. Pp. 1043. £7 10s. the set.

THE third volume and desk index now issued complete this work, of which the first two volumes were reviewed in THE LANCET, 1930, i., 866. The main subjects dealt with in the third volume are the thorax, the breast, the liver and pancreas, the rectum, the genito-urinary system, and the surgery of the central nervous system. In a work edited by Dr. Graham it is natural to turn first to the article on cholecystography in the section on diseases of the liver and bile-ducts. The author's fears that any reader might resent the amount of space devoted to this subject are groundless, for the pioneer of such a valuable method of examination is expected to give an authoritative account of its development, indications, and drawbacks. His descriptions are complete and very clear, and could not have been spared. The section on the breast is also full, is well illustrated, and contains a very readable account of the diagnostic problems of this difficult organ. The least satisfactory section in this volume, and indeed in the whole work, is that on diseases of the genito-urinary system. Starting on the assumption that urological diagnosis is essentially a specialty, the author attempts to set out general principles of diagnosis under the two heads of presumptive evidence such as should be gathered by the general physician, and positive findings which are the result of instrumental examination by a specialist. Even admitting that such a view may have its advocates, its exposition is lacking both in conciseness and clarity. This section consists solely of descriptive lists of the lesions of various parts of the tract, followed by extensive references to the literature in many languages, to which the reader must presumably turn for the information which he naturally expects the section to contain. A crowning incongruity is that this section, for whose synoptic form the only possible excuse would be lack of space, is followed by a chapter on bladder pressure in genito-urinary surgery in which nine charts of cystometrograms are given, whereas in the whole article on genito-urinary surgery there is only one picture of a cystoscopic appearance, and not even one of a pyelogram. The articles on the nervous system by Drs. Dandy, Adson, Dean Lewis and Ranson are admirable expositions of the subjects dealt with, and the illustrations in these sections are well chosen and reproduced. The inclusion of a desk index is a great convenience in a work of this size.

In the book as a whole there is much to praise. The majority of articles are clear and well balanced accounts by masters in their particular subject, and overlapping is in the main avoided. The paper, print, and illustrations could hardly be bettered.

A System of Clinical Medicine.

Eighth edition. By THOMAS DIXON SAVILL, M.D. Lond. London: Edward Arnold and Co. 1930. Pp. 1019. 28s.

THE special appeal of Savill's "Clinical Medicine" lies in the author's attempt to correlate all diseases by approaching them through their chief symptom The author tried to provide for the practitioner wh is faced with certain symptoms at the bedside, a guid which will lead him to the disease or syndrome fro which the patient is suffering. The book wa eminently successful in this object. Medicine ha however, expanded considerably, if irregularly, sinc the book was originally planned in one volume an it is now difficult to compress useful descriptions c the general features of each disease as well as suc aspects as prognosis and treatment into such a sma space. Within the limits available, however, th descriptions are admirable. Twelve pages have bee added to the eighth edition, and every part of th book has been revised. In addition to muc completely new matter the chapters on diseases of th lungs and liver have been recast, and the sections o the pancreas, mental diseases, urinary examinatio clinical bacteriology, and serum therapy have bee rewritten. The general editorship is still in th capable hands of Dr. Agnes Savill. The book i excellently produced, and the illustrations are vivi pictures, not mere blocks reproduced from catalogue or ancient text-books.

Intracranial Pressure in Health and Disease

Vol. VIII. of a series of Research Publication issued by the Association for Research in Nervou and Mental Disease. London: Baillière, Tinda and Cox. Pp. 519. 27s.

THE American Association for Research in Nervou and Mental Disease meets annually for the presentatio and discussion of original papers upon a commo topic, a practice which might with advantage b followed in other countries. It would be unreasonabl in a publication of the work submitted to look fo important discoveries. These cannot be produce to a conference time-table. The value of this, th eighth volume of the series of researches published b the Association, and its predecessors, lies in th opportunity given to the ordinary reader of bringin his knowledge of a subject up to date, an to the investigator of receiving some fertilisin impulse from the ideas of other workers at his ow problems.

This volume contains 31 communications divide into four sections. Section I. is devoted to the nature mechanics, and general investigation of intracrania pressure. H. S. Howe brings forward evidence i favour of the absorption of the cerebro-spinal flui into the cerebral capillaries instead of by the mor generally accepted route of the intracranial venou sinuses. L. H. Weed adds a further contribution t the many which he has made to this subject discussing, in particular, the influence of posture o cerebro-spinal fluid pressure. L. S. Kubie continue his important investigations of forced drainage of th nervous system, and there are other papers dealin with the experimental variation of the cerebro-spina fluid pressure. Section II. is concerned with studie of decreased and increased intracranial pressure an is the largest section in the book. D. Munro report an investigation of the cerebro-spinal fluid pressure i the newly-born, and advocates the reduction o raised pressures by lumbar puncture. J. B. Aye contributes an analysis of the lumbar cerebro-spina fluid in 67 cases of cerebral tumour. He emphasise the frequency with which some abnormality is found but does not consider that the findings are sufficiently

valuable to justify lumbar puncture in the presence of grossly increased intracranial pressure. C. Barnert advocates the determination of the systolic and diastolic blood pressure in the central arteries of the retina by the method of Magitot as an aid to the early recognition of increased intracranial pressure. W. R. Parker discusses the relation between the tension of the eyeball and the onset of papillœdema, the pathogenesis of which is well reviewed by C. Berens. The visual field defects associated with increased intracranial pressure are the subject of a communication by G. E. de Schweinitz. The two papers which follow are studies by G. B. Hassin and W. Penfield, of the pathological changes produced in the brain by pressure, and a paper on X ray changes in the skull concludes this section. Section III. deals with some aspects of intracranial tumours and includes a paper by W. E. Dandy on the mechanism and symptoms of tumours of the third ventricle and pineal body, with special reference to ventriculography in these cases. In Section IV. various methods of reducing the intracranial pressure are considered, the concluding chapter being on radiotherapy. Readers of the work will find in all the communications something of interest and value in the diagnosis and treatment of conditions causing increased intracranial pressure.

Photo-processes in Gaseous and Liquid Systems.

By R. O. GRIFFITH, D.Sc., and A. MCKEOWN, D.Sc., Lecturers in Physical Chemistry at the University of Liverpool. London: Longmans, Green and Co., Ltd. Pp. 691. 25*s*.

THIS volume maintains the high standard set in the text-books of physical chemistry which are being edited by Prof. F. G. Donnan. It contains nearly 600 pages and deals with only one aspect of physical chemistry—namely, photo-processes. The authors state that the foundations on which the present-day photo-chemists must build are those branches of modern physical theory which are concerned with the interaction of radiation and matter. The reader, then, will not be surprised to find that nearly one-half of this book is devoted to theories of atomic and molecular structure, atomic and molecular spectra, and photo-luminescence. The book gives a very comprehensive account of the photo-processes in gases and liquids, both on the theoretical and practical side. In the chapter on photo-stationary states the application of this theory to vision is ably discussed, but the reading is not easy, and readers must be prepared for a mathematical approach to the subject.

Angina Pectoris.

By HARLOW BROOKS, M.D., Emeritus Professor of Clinical Medicine, New York University. London: A. and C. Black, Ltd. 1930. Pp. 164. 8*s*.

So much has been written on angina pectoris that unless an author has something new to say, or at any rate believes that he can express the old views more clearly than did his predecessors, it is difficult to justify the production of yet another monograph on the subject. In the second chapter of Dr. Harlow Brooks's book we were led to hope that his own series of 350 cases would provide interesting material. Had he contented himself with giving a simple analysis of his findings in this group he would have made a useful contribution to the literature; but unfortunately he has preferred to rely chiefly on the observations of previous writers, and to treat the subject in a discursive fashion. In more than one place he fails to draw a clear distinction between ordinary paroxysmal angina and coronary thrombosis—the one aspect of the subject where a definite advance in knowledge has been made in recent years. The statement on page 65 that angina pectoris occurs almost exclusively in highly emotional and nervously sensitive persons is contrary to the experience of most clinicians. A long chapter is devoted to pseudo-angina pectoris, but it fails to give a well-balanced picture of the condition.

Heart Disease in Infancy and Childhood.

By CHARLES HENDEE SMITH, B.S., M.D., Professor of Clinical Diseases of Children, Columbia University; and LUCY PORTER SUTTON, B.A., M.D. London: D. Appleton and Company. 1930. Pp. 259.

THIS monograph deals not only with heart disease but with rheumatic fever in general; for, as the authors point out, rheumatic carditis is by far the most important type of heart disease in children. They rightly lay stress on the fact that acute rheumatism should be regarded as a general infection involving the joints, heart, and brain in varying degrees, and not as an acute arthritis in which cardiac involvement is a secondary complication. Arthritis, chorea, and carditis may all be primary lesions, and it is wrong to regard the last merely as a sequel of one of the other two. In the chapter dealing with the systematic examination of the heart, the usual routine of considering in turn the phenomena revealed by inspection, palpation, percussion, and auscultation is abandoned. In its place the authors deal with heart size, action, sounds and murmurs, describing the various criteria which yield trustworthy information about cardiac enlargement, disorders of the cardiac mechanism, and valvular lesions respectively. Some of the more conservative clinicians will doubtless regret this innovation, but generally it will be welcomed. In cardiology the introduction of new methods of investigation necessitates a reconsideration of the relative values of different diagnostic signs. Radiography, for example, has shown that the position of the maximal cardiac impulse is generally a more reliable guide than percussion to the position of the left border of the heart, and it is time, therefore, for percussion to take second place. Two useful chapters are devoted to the electrocardiograph and X ray examination, but surely it should not be necessary to discuss here the interpretation of the normal electrocardiogram. The proper place for this is in the text-books of physiology or electrocardiography, and it should already be familiar ground to the clinician who is specialising in diseases of children. The classification of heart disease adopted by the New York Heart Association has been followed, cases being graded in accordance with the severity of their symptoms. To the same source we are chiefly indebted for the organisation of coöperating agencies which fulfil such an important function in the after-care of cardiac cases.

This monograph is the eighteenth volume of the series on Clinical Pædiatrics edited by Dr. Royal Storrs Haynes. It is apparently sold only with its immediate predecessors in the series, entitled respectively Prepubescent Syphilis and Diseases of the Skin in Infancy and Childhood, which were reviewed in THE LANCET earlier this year at 48*s*. for the three volumes.

MEDICINE AND THE LAW.

Panel Patient and Charge for Fees.

ALTHOUGH each case is based upon its own peculiar facts and possibly no two cases are alike, the decisions of the Minister of Health upon allegations of malpraxis in connexion with national health insurance medical benefit are of interest to many members of the profession. In a recent instance the following facts were established. A domestic servant pricked her thumb, which became septic. Happening to visit a friend on the following Sunday, she was persuaded that she ought to see a doctor. She thereupon went to her friend's insurance practitioner; for some reason not made clear, she did not go to the practitioner on whose panel she herself was. The doctor was at dinner when the patient and her friend arrived. He examined the thumb, put some white powder on it, and told her to come back next day and bring her medical card. She did so; he then lanced the thumb and stripped some of the skin from the pad of it. He gave her Form G.P. 26 authorising her to obtain cyanide gauze and bandages. She attended daily for a fortnight and at frequent intervals for the next few months. The thumb was again lanced two days after the first visit. Two days later the practitioner officially notified the insurance committee that the patient had been transferred to his panel. Subsequently the practitioner sent the insurance committee Form G.P. 45, giving notice that he had rendered the patient professional services and asking for approval of proposed charges to her on the footing that he had rendered such special services as entitled him to make such charge. The local medical committee and the insurance committee both agreed that the services were not such as to entitle him to charge the patient. The treatment for acute suppurative tenosynovitis (on which the claim for a fee had been based) was not, in their opinion, a service involving the application of special skill and experience of a degree or kind which general practitioners as a class cannot reasonably be expected to possess. The Minister agreed and declined to refer the question to referees. The insurance committee therefore informed the patient that the service performed for her was one which came within the scope of medical benefit under the National Health Insurance Act and one for which she should not have been required to pay a fee.

Up to this point there was merely a difference of opinion as to the nature of services rendered. Later the medical practitioner contended that for the first five days of treatment the patient was his private patient. The inquiry committee found against him; the contention, they said, was inconsistent with the patient's evidence and with the use of Forms G.P. 45 and 26. The patient's employer was insured with a well-known company against Workmen's Compensation Act liabilities. The company paid the employer £25 in respect of the patient. The practitioner endeavoured to obtain payment of his fees from the company. The company declining to pay them, he then wrote a letter to the patient enclosing a detailed account of the services rendered in connexion with the injured thumb. "Excluding all those under the National Health Insurance Regulations, an inclusive fee of £30 would be very fair and reasonable, and I shall be glad of a settlement in due course." A copy of the letter was sent to the insurance company. The insurance committee decided that the practitioner "sought to obtain payment of money to which he was not entitled for treatment provide by him for the insured person concerned": th inquiry committee says this finding was ampl justified. The Minister dismissed the practitioner appeal, and the upshot of the case is that the pract tioner is ordered to pay £5 5s. towards the costs of th insurance committee on the appeal, a sum of £100 to be deducted from the remuneration payable t him, and he is formally warned that any recurrenc of similar conduct would be bound to reopen th question whether his continuance upon the Medic List is in the interests of the insurance medic service. The insurance committee's attempt t remove him from the List—a serious matter for practitioner with some 1200 patients on his panel- failed. There was no suggestion that he had neglecte his patients or tried to charge fees to other insure persons on his panel. He seems to have felt that h had a claim upon the £25 which the domestic servan had received from the insurance company. This, th inquiry committee considered, had been the motiv of his improper conduct. They point out, in fairnes to him, that all the steps taken to obtain paymen of fees were taken openly.

REPORTS AND ANALYSES

SPECIAL FINE OLD LISBON WINE (PRODUCE OF PORTUGAL).

(BARCLAY PERKINS AND CO., LTD., ANCHOR VAULTS, 5, CRUCIFIX-LANE, S.E.)

ON analysis this wine gave the following results:—

Alcohol by volume	16·6 per cent.
Equivalent to proof spirit	29·0 ,,
Total extractives	8·38 ,,
Consisting of sugar	6·5 ,,
Tannin, mineral matter and pectinous substances	1·7 ,,
Total acidity as tartaric acid	0·36 ,,

Preservatives were tested for with negative result The wine, which is of a rich ruby colour, woul appear from the analysis taken in conjunction wit its palate to be a pure wine of the port type. Whils its strength is a little below that of the usual run o ports, it may be considered a perfectly wholesom product, not tampered with or adulterated in any way At the present time the description "Lisbon Wine is somewhat under a cloud, as cases have bee reported in the coroners' courts of wines bearing thi name being prepared with methylated spirit. Suc synthetic concoctions have nothing in common wit the wine whose analysis appears above. Th Portuguese Embassy has given an assurance tha wines from Portugal are rigorously supervised an tested before being exported.

BARLEY SUGAR.

(MESSRS. BARKER AND DOBSON, LTD., EVERTON, LIVERPOOL.)

The barley sugar, which was transparent and of a dark amber colour, is conveniently packed in a glas bottle with precautions to avoid the admission o moisture, as it is decidedly hygroscopic. Whe analysed, the following results were obtained:—

Cane sugar	76·0 per cent.
Invert sugar	22·0 ,,
Moisture	2·0 ,,
Ash	0·05 ,,

The material had a slight but very pleasant flavou of lemon. The analysis shows that only materials o a very high degree of purity were used in the manu facture, and no confectioners' glucose is present The obvious care taken in the making and its ease o assimilation are points much in favour of this popula sweetmeat.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 20, 1930.

SURGERY OF THE SYMPATHETIC NERVOUS SYSTEM.

OPERATIONS have been performed on the sympathetic nervous system since the latter part of last century, but it is only within the last five years that this branch of surgery has shown any signs of bearing fruit. The Surgical Section of the British Medical Association chose the subject for one of their discussions at Winnipeg, and the proceedings (reported on p. 639) merit wide consideration because they touch on disease at many points and break the artificial boundaries of modern specialism.

Earlier operations on the sympathetic nervous system were for the most part concerned with division or removal of the cervical sympathetic chain. This operation was done for such diverse maladies as epilepsy, insanity, facial palsy, exophthalmic goitre, and angina pectoris. It was easy to perform and was not attended by any noticeable ill-effects, beyond slight alterations in the upper eyelid, pupil, and face of the corresponding side. For this reason the operation had a certain popularity although the benefits derived from it were mostly not obvious enough to ensure its general adoption. There is no need now to consider the various and even fantastic hypotheses on which the operation was based, except to say that cervical sympathectomy, as designed to cut afferent nerves of the heart for relief of angina pectoris, still has a certain vogue and is attended in some cases by relief to the patient. Leaving aside the operation of periarterial sympathectomy, which, as Dr. J. F. FULTON pointed out at the Winnipeg meeting, was largely based on false anatomical and physiological premisses, the next important event in the surgery of the sympathetic nervous system was in 1923 when J. I. HUNTER and N. D. ROYLE introduced the operations of ramisection. These operations were intended to relieve spastic conditions of the limbs, for, from their experimental work, HUNTER and ROYLE had been led to believe that the sympathetic nervous system influenced the tone of voluntary muscles. Their claims aroused much controversy. Undeterred by the untimely death of HUNTER or his own ill-health Dr. ROYLE has not spared himself in advocating his operation and has performed it in many countries. The subsequent condition of the patients has been reported on independently,[1] and the original experiments have been repeated and extended. The balance of opinion appears to be that influence of the sympathetic nervous system on the tonus of voluntary muscles is unproven and that the operation is not effective in relieving spastic conditions of the limbs. At the Winnipeg meeting, however, ROYLE reaffirmed his faith in the operation and in the underlying hypothesis and in this he was supported by some Canadian and American investigators. In addition he advocated cervical ramisection for the relief of writer's cramp, atypical neuralgia of the face, and retinitis pigmentosa. Whatever the outcome of HUNTER and ROYLE's original contentions may be, the profession is, as Lord MOYNIHAN pointed out, greatly indebted to Dr. ROYLE for beginning a new era of sympathetic surgery.

In the original cases of lumbar ramisection, though attention was focused on the state of the muscles of the lower limb, it was also observed that limbs deprived of their sympathetic fibres became much warmer, and that a patient who had formerly been constipated had after operation free and frequent action of his bowels. These observations could be explained by existing physiological knowledge and it was at once perceived that they might have wide application in surgery. By removal of the greater part of the sympathetic trunk so as to divide vasoconstriction fibres, A. W. ADSON was able to improve the circulation of the lower limbs and thus to treat successfully Raynaud's disease. Later he devised an operation that proved satisfactory for Raynaud's disease of the hands. He has extended the scope of these operations and has obtained encouraging results in certain cases of thrombo-angiitis obliterans, scleroderma, and chronic arthritis in patients with cold extremities. The improvement obtained in Raynaud's disease has been so marked as to make him believe that this condition is due to excessive activity of vasoconstrictor fibres. The studies of Sir THOMAS LEWIS appear to show conclusively that this is not true, for LEWIS has been able to produce attacks of vascular spasm, resembling typical Raynaud's disease, in limbs which have been deprived of their sympathetic nervous supply by Adson's operation. Although it is probable that the operation thus does not treat the cause of Raynaud's disease, yet there is no doubt, as LEWIS himself has clearly shown, that it improves greatly the circulation in limbs affected by vascular spasm and that it has won for itself an assured position in surgery.

Following the first ramisections R. B. WADE, with the help of ROYLE, performed lumbar ramisection on cases of Hirschsprung's disease. At Winnipeg he gave a convincing report of the value of the operation in this condition, and also in some cases of chronic constipation, and his results were confirmed by J. R. LEARMONTH. LEARMONTH has opened up a new field of sympathetic surgery by dividing the sympathetic nerve-supply to the bladder in certain cases of defective micturition following myelitis of the sacral cord or other lesions which affect the parasympathetic system. Remarkable results have been obtained and it is likely that the operation will prove to have wider application in the treatment of imperfect emptying of the bladder that is of nervous origin.

[1] See, for instance, THE LANCET, July 19th, p. 127.

These operations on the sympathetic nervous system are anatomical dissections of parts of the body which are not affected by disease, and they can be easily performed by any surgeon who has a proper knowledge of anatomy. But no justice can be done either to the patient or to the subject unless the surgeon devotes himself also to the physiological side of his cases. As Dr. W. J. MAYO suggested in his opening address at Winnipeg, there will be great opportunities not only of extending the science of surgery but also of making important contributions to human physiology. The earlier surgery of the sympathetic nervous system failed because it was based on imaginative thinking rather than on accurate studies, of which the work of LEWIS may be cited as a model. If the complexities of the subject are not ignored we may indeed be approaching what Lord MOYNIHAN termed an era of physiological repair.

THE FUTURE OF CONTRACT PRACTICE.

Dr. GRAHAM LITTLE'S address to the Paddington Medical Society last week has had a good press, and was in fact more piquant than the précis on which newspaper comment was based. He thought it probable that a system of medical service under State control would be pressed upon the nation by the Government in the near future, and that the medical profession would have to face a crisis as grave as that of 1912 when the National Insurance Act took form. Dr. LITTLE himself has small use for contract practice of any kind, which he regards as unsatisfactory to the patient because it means the introduction of a third party whose first consideration is seldom the patient himself; and unsatisfactory to the doctor because his work becomes stereotyped in the keeping of books and collection of statistics. In addition there is the drawback inherent in the panel system that it induces the patient to have recourse to his doctor unnecessarily. Dr. LITTLE thinks that all this has lowered the prestige of the profession, but, it may fairly be argued that insured persons are visiting their panel doctor more frequently because they value his services more, not less. The unnecessary visits, as the *Manchester Guardian* suggests, may be a sign that the working classes are gradually losing that terrible fatalism about disease which has so often led them to wait until the doctor is undoubtedly required, and therefore often too late. A preventive visit now may dispense with the need for nine curative visits later on. The facts to which the Government Actuary has been calling our attention are possibly the first indication of the principle of preventive medicine getting into national insurance practice.

The first intention of the Act of 1911, as stated in its title, was to provide for insurance against loss of health and for the prevention of sickness. The cure of sickness came second, and insofar as medical benefit deals only with established illness the intention of the legislature has proved futile. The workers themselves are taking cognisance of this difference between intention and realisation. At the recent Trades Union Congress in Nottingham, Mr. ERNEST BEVIN, speaking for the Transport and General Workers, described the result of the panel system as a tragedy of incompetence. The medical service we get to-day, he said, is not in line with the developments of modern discoveries in the medical world. Mr. BEVIN went on to remark that any medical service that does not provide for adequate diagnosis as its first principle is not achieving its object, and he ended with an appeal to the medical profession to join with Parliament and the Government departments chiefly concerned in bringing their combined experience and knowledge to provide a well-organised, well-developed, well-trained, and (he was prepared to say) well-paid medical service to protect the health of the people. He invited the British Medical Association to sit down with the trade-unions and hammer out the basis of such a service; and the Association has, in fact, just issued, in the form of a sixpenny 48-page booklet, its proposals for such a general medical service for the nation, with an invitation to public bodies to comment upon and criticise them. A fundamental principle of this scheme is a provision of diagnostic aids, available for every individual patient.

It is hardly to be doubted that any such general service will be in large part on a basis of contract. Contract practice has come to stay; it has always arisen at a certain stage of social development, and it was not the principle that was new in 1912 but the introduction of a central umpire into a system which up till then had been administered, for better or for worse, by little groups up and down the country. What the conditions of contract practice were 35 years ago may be read in a series of articles, entitled "The Battle of the Clubs," written on first-hand information by a special commissioner of THE LANCET, and published in 1895–96:—

> "Some of these clubs," he wrote, "are uncommonly ill-managed, in that all persons, no matter what their condition of health or their means, are invited to enroll themselves, that they may be treated medically for a penny or two a week, drugs included. In certain of these institutions the management of the association having been, and remaining, entirely in lay hands, the interests of the medical officer suffer severely. These gentlemen are treated badly by the persons to whom they dispense charity. Their emolument is very small, and their work is very hard. The patients who might reasonably be expected to pay them as private clients are not ashamed to join the charitable associations—charitable to all save the medical man—and may even want to have their wives, children, immediate relations, and occasionally the stranger within their gates, all treated in return for one payment."

It was not the principle of contract practice such as this that was brought in by the Act of 1911, but rather the opportunities of collective consultation (called rather provocatively collective bargaining) which have increased the status of the contracting doctor and raised the average quality of the treatment given to an extent which is only overlooked by those who have short memories or who are politically biased. Mr. E. B. TURNER,

who is admittedly not enamoured of contract practice, told the meeting at Paddington that, in his opinion, the National Insurance Act had been working well for all parties in rural districts, although in towns and urban areas its success was less evident.

Any further extension of contract practice need not, however, necessarily be on a compulsory basis. In London, for instance, there has been growing up a voluntary contract system, run by doctors for doctors, which is described as combining the advantages of the national scheme without its disadvantages. For a capitation fee of threepence per week, paid in full to the doctor, the subscriber becomes entitled to medical and surgical treatment within the competence and skill of a general practitioner at the surgery or at his house, including all needful medicines. The scheme is growing steadily in London, where there are now 11,255 subscribers, a large proportion of them being in the Paddington and Kensington areas; and there are 30 or more such services now running in different parts of the country. The experience of those actually engaged in these services will be an important element in any contemplated change in the near future. A Labour Government, acting on the advice of its medical advisory committee, may come to some decision which will alter the whole practice of medicine in these islands; but history suggests that adjustments of this kind come gradually by common consent. The large majority of practitioners are party to a decision that the time is now ripe for the inclusion of dependents of insured persons under the national scheme. If there are alternatives which are working well in practice, they should be considered before any action is taken. Paddington is happy in having a forum for practitioners of all shades of medico-political complexion where an endeavour is being made to work out some agreed basis of procedure. The need is great for similar action in other areas.

THE BACTERIOPHAGE AND THE TREATMENT OF CHOLERA.

THE most interesting property of the bacteriophage, from the point of view of practical medicine, is its effect in the living body. It may be recalled that the bacteriophage is a principle which brings about the solution of bacteria and under favourable conditions their more or less complete destruction (the Twort-d'Herelle phenomenon). The nature of this "principle" has been ardently debated. If it is not a living entity, in our ordinary understanding of the word, its characters so closely resemble those of living organisms that in the absence of contrary proof the definition may be allowed to stand. The affected bacteria seem to become diseased; their osmotic tension increases; they swell, burst, and disintegrate. In the resulting solution the lytic principle—the bacteriophage—is present in an increased amount. The general phenomenon is nowadays a commonplace in the test-tube, and most of D'HERELLE'S contentions concerning its characteristics in this environment have been shown to be substantially correct. But in respect of its occurrence and effect in the living body very diverse opinions have been held. D'HERELLE has never ceased to teach that bacteriolysis takes place in vivo exactly as in vitro, and that it alone causes recovery from certain diseases. Nay, more, he is convinced that epidemics are controlled by this same factor. In his opinion a patient's recovery is brought about by intracorporeal genesis of a bacteriophage capable of destroying the organisms, whilst the cessation of an epidemic is due to the spread of this bacteriophage among the exposed population. This theory of infection and immunity, which is peculiarly D'HERELLE'S, has been applied by its author mainly to intestinal infections, since the bacteriophage is normally an inhabitant of the bowel; but it has also been extended to include other infections, such as those due to the staphylococcus and the hæmorrhagic septicæmias (plague and barbone of the buffalo). In the hands of D'HERELLE and certain others bacteriophage therapy has yielded very valuable results. On the other hand, many investigators—and probably a majority—report that it has had no influence of any significance, either experimentally or in practice.

It might well be argued that if one disease is more suitable than another for testing the efficacy of this treatment it is cholera. Here we have an acute infection in which the germ does not pass beyond the intestinal walls, and the conditions are, therefore, favourable to the working of specific antibacterial agents in the lumen of the gut. Moreover, the organism is relatively delicate and particularly apt for bacteriolysis, as was shown long ago by the classical studies of METCHNIKOFF and PFEIFFER, and others. We therefore turn with great interest to the reports of an investigation of the action of the bacteriophage in cholera which has been carried out by D'HERELLE, with the assistance of R. H. MALONE and M. N. LAHIRI. The work was done at the instance of the Government of India, and was financed by the Indian Research Fund Association. The results obtained, which constitute the most serious contribution to the literature of the subject which has yet appeared, have now been published in a special memoir.[1] This is divided into three parts, one of which deals with the bacteriology and bacteriophagy of cholera, one with the phenomena of recovery and the results of treatment, and the third with epidemiology and prophylaxis. The authors find that D'HERELLE'S claims for the efficacy of the lytic principle in the body are very fully confirmed. In the first instance they studied 23 cases of cholera which were treated at the Campbell Hospital, Calcutta, by the approved current method—that of Sir LEONARD ROGERS. Seven of the patients died. No specific bacteriophage therapy was attempted, and the observations were simply confined to examination of the dejecta for

[1] Indian Medical Research Memoirs. No. 14. By F. d'Herelle, M.D., Professor of Protobiology, Yale University; Major R. H. Malone, M.D., I.M.S.; and M. N. Lahiri, M.B. 1930.

vibrios and bacteriophages in order to demonstrate what was the normal mechanism of recovery. It was found that recovery was regularly associated with the appearance of a specific bacteriophage of high activity in the stools, whereas in fatal cases the bacteriophage was absent or showed little activity. "In all patients in whom the virulence of the bacteriophage (for the vibrio) is exalted and reaches a sufficiently high degree . . . recovery is the rule. The duration of the disease depends on the rapidity of the exaltation of the bacteriophage and the degree of virulence attained." Holding this view of the mechanism of recovery the authors of the memoir deny the intervention of humoral immunity as usually taught in any form. For them such serological signs of immunity as may accompany recovery are epiphenomena and have little or no causal relation to the fact of recovery.

From these observations the investigators proceeded to the direct examination of the effect of the bacteriophage in treatment. The patients were treated in their own homes and were to some extent selected, since they were all persons who had consented that the method should be used exclusive of all others. D'HERELLE argues that such selection is, if anything, inimical to good results, since only those in desperate case will agree to be the subjects of experiment; but of course the opposite is arguable too. Other cases in the same village, treated only by prevalent methods of oral medication, served as controls. The bacteriophage treatment, which was carried out by MALONE, consisted of an initial dose of 2·0 c.cm. of bacteriophage preparation in 10 c.cm. of water, followed by repeated administration of a similar preparation during the next three hours. When necessary the same procedure was carried out on the following day. Almost all the cases (198 in number) were derived from nine relatively small outbreaks in Punjab villages of from 450 to 3000 inhabitants. The results may be summarised as

Total cases 198

Treated with phage ..	74	Not treated with phage	124
Died	6	Died	78

This gives a death-rate of 63 per cent. in the untreated cases, which is about the normal death-rate from this disease, as against one of approximately 8 per cent. in those who received the specific treatment. A further analysis of the figures, with reference to the time of commencement of the specific treatment, gives results yet more favourable to the bacteriophage, in cases in which the treatment was commenced early. We note the curious fact which may have much significance, that where the bacteriophage was given subcutaneously as well as by mouth, the results were nothing like so good as when it was given by mouth alone.

We have several times had occasion to criticise reports on the use of the bacteriophage in therapeutics, and to throw doubt on their statistical value. The present figures are very striking and we have no complaint to make of their presentation; but it is regrettable that an even larger number of cases were not submitted to treatment before any final conclusions were drawn. It is not made clear whether the experiment was carried out in the season of greatest incidence of the disease—although this seems to be so from the epidemiological studies of RUSSELL and SUNDARARAJAN [2]—or in a period of lesser activity; nor are we able to judge how long the epidemics had been going on before treatment was started. These factors are of prime importance in assessing the value of the method. We also have in our hands a paper by L. SOUCHARD,[3] who, following D'HERELLE'S technique, treated 27 cases of cholera in Cochin China with far less fortunate results, in that only three of the patients survived. These circumstances make it all the more unfortunate that in a country where 40,000 deaths from cholera may be registered in a month in a single province [2] the total number of cases treated in what should be a vital inquiry did not exceed 74, while this essential part of the investigation only lasted six weeks.

On epidemiology and prophylaxis the views expressed by D'HERELLE and his colleagues are as heterodox as those already quoted. They believe, as we have said, that the epidemic is controlled and terminated by the agency of the bacteriophage. In nature this is brought about mainly by pollution of the water-supply by excreta of convalescents who harbour non-virulent vibrios which are similar to the variant types which may be produced in the test-tube by bacteriophagic action. Such vibrios are associated with a bacteriophage which preys upon them and is similarly potent for the virulent *V. cholerœ*. In India fæcal pollution of wells is a normal event, so that such a bacteriophage is readily disseminated. When this happens, it is maintained, the epidemic ends. So certain are the authors that this is the mechanism of recovery and immunity that they say that the vibrios recovered from convalescent carriers are always avirulent and associated with a bacteriophage, so that "it is enough to introduce a carrier into a community of susceptible individuals for the community to become entirely resistant." This is not merely heterodox; it is revolutionary. We may recall from the work of others, which may have some bearing upon the virulence of vibrios in carriers, that the fact that the severity of the cases declines as the epidemic progresses is well attested, whilst the special prevalence of non-agglutinating vibrios in epidemics has been repeatedly observed. D'HERELLE'S contention means that the disease is only transmitted by the incubating, early, or fatal case, and that in the absence of these there can be no cholera. A patient, according to this thesis, is only infectious until bacteriophagy takes place in his gut; he then recovers, becomes non-infectious, and a disseminator of a beneficent bacteriophage. The position of the variant and inagglutinable strains of vibrios is, of course, an old problem, and while D'HERELLE'S theory gives an entirely plausible explanation of their occurrence and their significance in convalescents, it must be remembered that the appearance

[2] Indian Medical Research Memoirs. No. 12. By Lieut.-Col. A. J. M. Russell and E. R. Sundararajan. 1928.
[3] Ann. de l'Inst. Pasteur, Feb., 1930, p. 126.

of a bacteriophage in recovery and its absence in fatal cases does not prove the causal relationship which he assumes. Evidence of this relationship may be supplied by the results of treatment, but it would also be useful to inquire into the relationship of the variant inagglutinable vibrios of low virulence, which are said to result from bacteriophage action, to the variants produced in bacteria by other environmental alterations such as the action of immune sera.

The report of D'HERELLE and his colleagues is bound to arouse intense interest, not only because cholera is an urgent problem, but chiefly because of its fundamental bearing on the problems of immunity and epidemiology. The pronouncements of the authors will be criticised as dogmatic for they show an airy disregard of work that conflicts with their own views. If their claims are confirmed a great and fundamental advance will have been made in the control of epidemic disease; but in making these claims they have undertaken a heavy responsibility.

ANNOTATIONS

THE BOARD OF CONTROL AND THE MENTAL TREATMENT ACT.

THE early mental case will always be a perplexing problem to the general practitioner and to the local authorities; there can be little doubt that it is to the public interest that much better facilities for early treatment should be provided than exist at present. Unfortunately this provision is costly and great care must be exercised in selecting cases likely to benefit. The Mental Treatment Act of 1930, the major part of which comes into force on the first day of 1931, permits a variety of means. Local authorities may establish admission hospitals on the basis of the Maudsley Hospital in London or they may contract with a general hospital for special pavilions. It is to be hoped that in future the mental wards in the old poor-law institutions will no longer be used for temporary treatment and observation of all cases indiscriminately. The school mistress with melancholia, the degraded alcoholic, the court case on remand, the senile dement—these should never be nursed in the same observation ward, as too often happens at present. The problem is admittedly difficult but the new Act makes its solution more possible. It is natural that the report of the Board of Control, which we summarise on another page, should open with a reference to this Act, since that measure has gone so far towards consolidating the ideals which the Board have at heart. They believe that the Act is epoch-making for several reasons. It is an encouraging sign of convergence between medical and lay opinion in matters connected with mental disorder. Voluntary patients who for long could be received in registered hospitals and licensed houses may in the future be received in our public mental hospitals; temporary patients may also be received for treatment without certification, so that the mental hospital will approximate much more closely than heretofore to the general hospital. The admission of these early cases, however, must be contingent upon the provision made by local authorities; the Board have no power to force an authority to provide accommodation, they can only criticise this accommodation in the interest of the patients. The impetus for better treatment and better building must, in the future as in the past, come from local public opinion. Another welcome feature in the Act is the ability to approve accommodation for mental patients in general hospitals, thus removing compartments which have so long been almost watertight. The Board attach great importance to the local survey of requirements which the Act enjoins, expressing their hope that the survey will envisage the mental health of the community as a whole and the needs of the future. If the Board have their way it will become possible for medical officers of mental hospitals to staff the new out-patient clinics recognised by the Act and for a skilled psychiatrist to be appointed as an after-care officer, at least in larger areas. Not the least important provision of the Act empowers local authorities to undertake or support research work which has hitherto been gravely restricted by their lack of power to make staff appointments. Hitherto it has been inadmissible for several mental hospitals to establish and maintain a central laboratory; the near future may see group laboratories linked up with universities or medical schools in a chain of research throughout the country.

AN ENGLISH HEALTH FILM.

Leyton Borough Council are responsible for the production of a propaganda film which was shown with success at the local picture houses during Health Week. The staging and preparation of the film has been the work of Dr. J. E. Cheesman, who has the unusual theory that a health film should deal with health rather than disease. Under the title "Better Health," the film is intended to appeal to all those who are interested in children and their welfare. In spite of the exigencies of the English climate the photography is good, and attention is captured at the outset by a few scenes from prehistoric life borrowed from the American production of "The Lost World"; absurd monsters are seen rooting in the primeval mud, and man—a healthy-looking savage—holds his own against disaster by his superior intelligence. The moral is stressed by a glance at a modern bacteriologist at work in his laboratory, and the scene passes on to school medical inspections, children at play, open-air classes, dental inspections, and a realistic representation of a dental extraction under gas on an expectant mother. At one point a company of children are seen under the spray bath, and at another the use of the fountain drinking tap—for which no cup is necessary—is demonstrated; a healthy disregard for nudity is exhibited by all the children photographed, who take their sunbathing as a matter of course. Boys at carpentry and girls at the washtub show an interest in their tasks, and the film closes with some hundreds of healthy children massed and cheering. The difficulty always encountered in this form of film work is to make the subject matter at once instructive and palatable to the public. Most patrons of the cinema have a natural resentment against education disguised as entertainment, and since cinema proprietors must supply the demand with which they are faced it is not easy to make a propaganda film which will pay its expenses on the

road, while the initial outlay must always be considerable. The Leyton film, Dr. Cheesman tells us, has satisfied nearly everybody; it was accepted by three film proprietors in Leyton during Health Week, and has been let out to other authorities since. Alterations and improvements can be made at any time when necessary, and it remains the property of the Council for use whenever required. We have also seen an American film of a similar type, entitled "A Day at Merrill Palmer School," which shows the routine in a nursery school. While the photography is even better than that of the English film, it suffers from interruption by excessive captions, and the interest is not so well sustained. One is struck by the large number of helpers who appear to be available, and who sometimes are present in the proportion of one helper to three children—a state of affairs which it is hard to imagine we shall ever rival in this country.

PROBLEMS OF BIRTH CONTROL.

THE seventh international Birth Control Congress was held at Zürich from Sept. 1st–5th. Though it was attended by representatives of eight different countries, the main contribution was made by speakers from Great Britain, the United States, and Germany. In Germany birth control is a political issue. It is opposed by conservatives and nationalists for several reasons of which, according to Dr. K. Soloweetshik (Leipzig), not the least important is "the resentment aroused in government and medical circles by the unfavourable attitude of the rest of the world towards Germany." In the minds of socialists, however, birth control is an essential part of a wider movement aspiring towards political and moral emancipation. It is carried forward on an emotional wave which also sustains the issues of free-love and abortion. Much fervour was expended by German speakers upon this last subject. One of them, Dr. W. Pust, stated that between 1900 and 1930 Germany lost five times as many lives through the practice of abortion as she lost in the late war; that the number of abortions induced annually was greater than the number of living births; and that it was unusual for a German married woman not to have had an abortion at least once in her lifetime. By many German speakers it was vehemently contended that a modification of the German penal code in regard to abortion would be followed by an amelioration in maternal health comparable to what was reported by Dr. Martha Ruben-Wolf to have taken place in Soviet Russia.

Two obstacles to the progress of birth control in Germany were described. The first was a paragraph of the "doctor's oath" in which the individual doctor is exhorted "to refrain from all things tending to reduce the population or strength of the people." The second is a clause included in the new draft of the penal code of the German Reich that: "the public recommendation of articles to be used for immoral purposes renders the offender liable to not more than two years' imprisonment." Hence the birth control movement in Germany is at an earlier stage than in this country. It is still, largely, in the crusading stage, and it has not yet become detached and self-critical.

As regards contraceptive methods and technique, several points of interest arose, and we will comment on two of them. In the first place the increasing experience of different investigators of the Gräfenberg ring is tending to weaken rather than strengthen confidence in the suitability of this method for any but carefully selected cases. In a paper devoted to his own method, Dr. Gräfenberg stated that he had now fitted 1331 patients with his various intra-uterine appliances. With the silk stars and rings, now abandoned, he had had 3·1 per cent. of failures; with the silver ring he had had 1·6 per cent. But his figures were not presented in anything approaching the detail that the conference would have liked. Dr. J. H. Leunbach (Denmark) reported having fitted the ring in 176 cases. From 23 of these it had subsequently to be removed, and from 22 it came out by itself. Four women lost the ring without knowing it; one woman became pregnant despite the presence of a ring which fitted well. In a much smaller series (15) Dr. Helena Wright (London) reported several unanticipated sequelæ, but the reports of Dr. Norman Haire (London, 270 cases) and Dr. Norbert Neufeld (Breslau, 30 cases) were more favourable. The general opinion of the conference seemed to be that the method best adapted to the requirements and capacity of the majority of women is a combination of a vaginal pessary—the Ramses and the Mensinga being the most favoured—and a spermicide. As regards the optimal size of pessary for average women—about which there has lately been correspondence in our columns—the statistical experience of the birth control clinics of the United Kingdom and United States is unambiguous. It is to the effect that large sizes are fitted in preference to small. Thus, at 26 American clinics through which had passed 36,804 women, the average sizes of pessary fitted were Nos. 70, 75, and 80. At 16 British clinics that had dealt with 45,321 women, the average sizes were 70, 72½, and 75. Of the 42 clinics whose records of sizes were submitted to the conference, the Cromer-street Clinic, in London, and the American clinic at Reading, Pennsylvania, fit the smallest sizes. The average sizes here used are 10–15 mm. smaller than the average for all the clinics.

DEATHS UNDER SPINAL ANÆSTHESIA.

THE statistics of anæsthetic fatalities are notoriously unsatisfactory. The data on which conclusions are based are at once insufficient, numerous, and variable. The cases never afford really fair comparison between the various methods and drugs, for either the patient or the operator or the operation is always different. These facts are well demonstrated in a paper[1] on spinal anæsthesia fatalities which contains a number of interesting and instructive instances of deaths associated with this form of anæsthesia. In the vast majority of the cases cited the facts recorded are so meagre that it is quite impossible to form any valuable surmise about the real cause of death. In some instances spinal anæsthesia was used for operations not usually held to be well adapted to that method. Amputations of the breast, for example, provide one or two of those quoted, and another perhaps more notable instance is that of a boy of 9 years who underwent tonsillectomy under spinal anæsthesia. He was given 150 mg. of neocaine dissolved in 6 c.cm. cerebro-spinal fluid, the injection being made between the second and third lumbar vertebræ. Satisfactory anæsthesia of the entire body resulted, the operation was satisfactorily performed, and the boy returned to bed. About ten minutes later he was put in the sitting position to facilitate expectoration of blood. After about two minutes respiration ceased and resuscitation efforts failed. Here it appears that the fatality will be attributed to the faulty position instituted by

[1] Amer. Jour. Surg., August, 1930, p. 234.

the nurse on a patient still affected by the spinal injection. The authors of the paper, H. Koster and M. Weintrob, have done valuable work in spinal methods, and there is much truth in what they say about the fallacies of statistics tending to show the superior safety of inhalation anæsthesia. We entirely agree with their remark that "the value of any statistical study (regarding anæsthetics) depends less upon the tabulated figures than upon the thoroughness with which all the modifying factors are set forth and discussed." They make no attempt to explain the mechanism of death in those rare cases, some of which are cited, in which a healthy person receiving only a usual dose or merely a spinal puncture dies suddenly. They are to be compared, we suppose, with similar instances in the history of inhalation anæsthesia in which little or even none at all of the anæsthetic has been inhaled when death occurred.

AUTOPATHOGRAPHY.

THE word "autopathography," according to Dorland's Medical Dictionary, connotes a written description of one's own disease. The death of Dr. Leonard Mark has drawn attention to his account of his own sufferings from acromegaly. It is not easy to see how, apart from his skill as a trained observer, the account would add to our knowledge, but his experience probably added to his understanding of the sufferings of other victims of the same disease and the episode prompts inquiry how far subjective experience of pain or illness is helpful or necessary to the physician. To some degree such experience is universal, and a patient's physical pain or discomfort belongs to a world with which we are all familiar. It is difficult, indeed, to conceive that pain in others could be understood by one so constituted as to be incapable of feeling such pain himself; but when we come to the world of mental symptoms we find the conception necessary, for there are not only degrees but qualities of mental pain to which most of us are strangers. A vigorous movement in America and this country towards the advancement of mental hygiene received its stimulus from the experience, as an asylum inmate, of Clifford W. Beers, who after recovery brought to the movement the lessons derived not only from his physical but his mental sufferings during the illness. It is plain from his account that none but an experienced psychiatrist could have realised the quality, or even the existence, of his mental distress, and we can understand why the lack of such realisation in bygone days was associated with harsh treatment of the insane. When, however, we turn to the minor psychoses we find that lack of training has left each of us free, either to despise the neurotic patient as a more or less wilful nuisance, to regard him as in need of nothing more than cajolery or encouragement, or to study him objectively as a problem in which sequences of cause and effect are of scientific and practical interest. Evidence of these reactions can be seen at times in our own columns, and the neurotic patient himself quickly becomes a shrewd judge of the temperamental qualities of his physician. Jung believes that each temperamental type has its own "Weltanschauung," and that only the people whose outlook upon the world is similar can really understand one another. The cheerful and easily adjusted extrovert physician will fail to make contact with the doubting and overscrupulous introvert, and it is an observed fact that some physicians never hear of symptoms that are freely poured into the ears of their temperamental opposites. The symptoms of some of the minor psychoses are so irrational that, in the absence of previous instruction or subjective experience, only close acquaintance with the patient will convince the observer of their importance. Even then it will depend upon his own temperament how much he profits by the experience; he may learn to seek for similar phenomena in other patients or still regard them as curiosities.

Dr. Mark's story could be read with understanding by all medical men and women. An intimate account of neurotic sufferings would be incredible nonsense to some, some would understand it by their subjective experience of lesser troubles of the same quality, but few could appraise it and put it in perspective with the whole subject of the minor psychoses. Thus our understanding of some patients is affected by differences of temperament and inner experience that scarcely touch our attitude to physical suffering. Insanity has been lifted into the objective plane and temperamental differences in medical observers have little influence; improved instruction is tending towards a similar objectification of minor mental disorders, and we look forward to the time when affective reactions will have no influence upon the handling of the neurotic patient.

PUBERTY AND MATURITY.

MANY of the obscurities of sex and of the nomenclature of familiar sexual processes have been cleared up in recent years. The presidential address of Prof. F. A. E. Crew to the Second International Congress for Sex Research, which was held in London from August 3rd–9th, helps a good deal to clarify ideas about the onset of sexual activity, especially in the female. He makes it clear that "puberty" and "maturity" are not the same thing; in any exact analysis they must be distinguished. Puberty is the stage in individual development characterised by the ability to produce functional gametes, and by the desire and capacity to play the appropriate rôle in sexual congress; maturity is the stage characterised by the exhibition of the maximum fertility ratio, in the female by the ability to produce viable offspring and to rear them. Puberty, in short, equips the individual for fruitful mating, maturity for efficient reproduction. It is obvious that human material must necessarily be very unsatisfactory for the exact analysis of these subjects. Prof. Crew as a geneticist is particularly interested in the hereditary factors, and, as he points out, mankind is everywhere so genetically mixed that really pure stocks are not available for the examination of such a simple point as the age at which menstruation begins. A great many data have been collected on the subject; it seems clear on the one hand that environmental conditions of climate and so on have a definite effect, and on the other that the inborn constitution of the individual also has an influence. Thus Bolk, in Holland, found that the average age of the onset of menstruation was about ten months earlier in those whom he classed as blondes by their eye colour than in brunettes. For the investigation of maturity, human material is plainly useless. Prof. Crew, therefore, has undertaken precise observations on colonies of mice kept under controlled environmental condition in his department in Edinburgh, and they bring out very clearly some of the points which he wants to emphasise. In 100 female mice the first œstrus —i.e., puberty—occurred at various times between the twenty-eighth and seventy-sixth days of life. In 20 of the animals it was not followed by mating, and among the 80 in which mating occurred pregnancy

followed in only 24. Of these, seven died and four ate their young soon after birth. In the same mice when they were six months old pregnancy followed 80 to 90 per cent. of matings, and successful pregnancies and rearings were the rule. Pregnancy, therefore, is not only relatively rare when mating occurs immediately on the achievement of puberty, but it is also relatively dangerous. Turning next to the problem whether these events are controlled by genetic factors, Prof. Crew separates the mice into two inbred stocks, one white the other coloured, each of which may be assumed to be approximately pure genetically. In two successive periods of observation he found that puberty arrived earlier in the albinos than in the coloured, the best experiment giving a mean of 39 days for the albinos and 52 days for the coloured. Since œstrus recurs regularly once it has begun, and since the imperfections of pregnancies following the first œstrus are the same whether that occurs early or late, it follows that early and late sexual maturity are constitutional characters, and a preliminary analysis suggests that earliness is dominant to lateness.

The transition from puberty to maturity may then be expressed as the series (1) œstrus without mating, (2) mating without pregnancy, (3) pregnancy without viable offspring, and it seems likely that the successive steps ultimately depend on the development of the full functional activity of the pituitary. There are hardly any data which enable us to judge whether the mouse results may be transferred to man; general experience certainly suggests that they may, and it is at any rate known that very youthful pregnancies are associated with an excessive maternal mortality in both species.

THE ALKALOIDS OF ERGOT.

AN important paper, shedding new light on the alkaloids of ergot, has recently been published by S. Smith and G. M. Timmis.[1] In 1906, G. Barger and F. H. Carr isolated an amorphous but highly active alkaloid, ergotoxine, which was generally believed to be the specific alkaloid of ergot until 1921, when K. Stoll isolated a crystalline substance of slightly different composition which he called ergotamine. Since both of these substances had the same physiological properties, it was believed by some that ergotamine, being crystalline, was the true active principle, but the relation between them has hitherto been very mysterious, more particularly because other workers failed to obtain ergotamine. This failure was explained by Stoll as due to insufficiently protective methods of extraction. Smith and Timmis have now obtained crystalline ergotoxine, crystalline ergotamine, and also the inactive substances ergotinine and ergotaminine in crystalline form, and find all four to be pure and different. While ergotamine readily crystallises from many different solvents, ergotoxine only crystallises from one or two, benzene and its simple homologues and carbon bisulphide. More interesting is the fact that when Smith and Timmis apply either Stoll's own process or Kraft's process to the official ergot of rye, no matter what its country of origin, they always get ergotoxine. But it occurred to them that ergot grows on other grasses besides rye, and they find that when they extract the unofficial ergot of New Zealand tall fescue (festuca) by Kraft's process, they get ergotamine. These results suggest that the method of extraction has little to do with the alkaloid obtained, and that the variety of the ergot has everything.

[1] Jour. Chem. Soc., 1930, clxxx., 1390.

Hence ergotoxine and ergotamine are to be regarded as the active principles of two different kinds of ergot, different in the same way as the official *Strophanthus kombé* is different from the unofficial *S. emini*. Ergotoxine appears to be the true active principle of the official ergot of rye, while ergotamine comes from unofficial ergots.

"GENEVA PLACES."

IT will be remembered that the French delegation to the Naval Conference last spring put forward proposals for "humanising" submarine warfare. Those who retain any interest in such regulation of the game of war will find further food for thought in a paper[1] in which Dr. G. E. de Metz makes some suggestions for the preservation of non-combatants. Dr. de Metz is much impressed by the increasing risks they run from aerial and gas warfare. He therefore advocates the establishment and organisation in peace-time of neutral zones in each country, into which certain classes of non-combatants could be withdrawn in the event of war. He proposes that these areas should be called "lieux de Genève," and that pregnant women, mothers with young children, the aged, cripples, and the sick and wounded should be provided with special non-combatant certificates by the medical authorities, and concentrated in such sanctuaries, which would be neutralised by previous agreements between the belligerents. Each zone would be under the control of a neutral whose duty it would be to see that his area was not used for military purposes, and to prevent persons not furnished with non-combatant cards from using the area. The "sanction" against abuse of any zone would be its declassification as a neutral zone, and the "sanction" against its attack by the enemy would be reprisals against a similar "Geneva place" in the enemy's territory. Dr. de Metz thinks that public opinion may come to demand a gradual extension of the protection afforded by such places to larger and larger classes of non-combatants until the wheel turns full circle, and we may revert to the mediæval conception of war as a matter for professional soldiers or champions only. This is a pleasant change from the realist view of international struggles, and we look forward to the time when a soldier will have to produce his "combatant's card" before being allowed to proceed to the deserted area which has been allotted for the battle.

Dr. W. Norwood East has been appointed one of His Majesty's Commissioner's of Prisons and a Director of Convict Prisons.

THE annual general meeting of the Medical Defence Union will be held at 49, Bedford-square, London, on Thursday, October 2nd, at 4.30 P.M.

[1] Presse Méd., July 26th, p. 1021.

DONATIONS AND BEQUESTS.—Mr. T. W. G. Hewitt, of Weelsby Hall, near Grimsby, left, among other bequests, £20,800 to the Grimsby and District Hospital, including £20,000 for the endowment fund.

Sir William Morris, who has already given £90,000 for the purchase of the Radcliffe observatory site on which additional hospital buildings will be erected in connexion with the Radcliffe Infirmary, has completed the purchase price by an additional gift of £10,000. Sir William Morris's gifts to the infirmary, of which he is president, amount to £150,000.

OPENING OF THE MEDICAL SCHOOLS.

In connexion with the opening of the session at the London Medical Schools, the following arrangements are announced :—

Charing Cross Hospital.—Dr. J. M. H. MacLeod will distribute the prizes on Saturday, Oct. 4th, following tea at 4.30 P.M. The dinner of past and present students will take place on the same day at the Royal Adelaide Gallery Restaurant (Gatti's), opposite the Hospital, at 7.30 for 8 P.M., with Mr. E. B. Waggett in the chair. A special post-graduate course will be held on Oct. 4th and 5th.

Guy's Hospital.—The winter session will begin on Sept. 30th, and the opening address will be given on Tuesday, Oct. 7th, at 3 P.M., in the Physiological Theatre of the Medical School by Lord Moynihan.

King's College Hospital.—This school has now completed a hundred years' work, and an account of this will be given by Dr. Raymond Crawfurd, on Oct. 1st, at the opening ceremony of the winter session, when Dr. G. F. Still will take the chair at 2.15 P.M. The centenary dinner, at which Sir StClair Thomson will preside, will be held at 7 P.M. for 7.30 P.M. on the same evening at the Connaught Rooms, Great Queen-street, W.C.

London Hospital.—The old students' dinner will be held at the Trocadero Restaurant, Shaftesbury-avenue, W., on Thursday, Oct. 16th, at 7.30 P.M. for 8 P.M., with Sir Wilfred Grenfell in the chair. A post-graduate course, like the one arranged last year, will be held at the hospital from Oct. 15th to 18th inclusive.

Middlesex Hospital. — The opening ceremony of the winter session will take place at the Queen's Hall, Langham-place, on Oct. 1st at 3 P.M. Mr. Arthur Greenwood, Minister of Health, will distribute the prizes, and Mr. Eric Pearce Gould will give the introductory address. The annual dinner of past and present students will be held at the Savoy Hotel at 7.30 P.M. on the same day.

Royal Free Hospital.—The inaugural address and prize-giving will be held on Oct. 1st at 3 P.M. The address will be by Miss Maud Chadburn, senior surgeon to the South London Hospital.

St. Bartholomew's Hospital.—The old students' annual dinner will be held in the Great Hall of the Hospital at 7 P.M. on Oct. 1st, with Mr. L. Bathe Rawling in the chair.

St. George's Hospital.—On Oct. 1st, at 3 P.M., Lord Riddell will give an inaugural address at the annual prize distribution in the Board Room. Dr. James Collier will take the chair at a dinner, to be held at 7.15 P.M. for 7.45 P.M., on the same day at the Hyde Park Hotel, Knightsbridge.

St. Mary's Hospital.—The annual dinner of past and present students will be held at the Trocadero Restaurant, at 7 P.M., on Friday, Oct. 3rd. Dr. Reginald Fuller will take the chair. A special post-graduate course will be held from Oct. 3rd to 5th in the Library of the Medical School, beginning at 10.15 A.M. each day, and open to all medical practitioners without fee.

St. Thomas's Hospital.—Dr. R. Muzio Williams will preside at the annual dinner of old students to be held at St. Thomas's House, at 7.30 P.M. for 8 P.M., on Oct. 3rd.

University College Hospital.—The winter session will begin on Oct. 1st. The annual dinner of past and present students will be held at the Hotel Victoria, Northumberland-avenue, W.C., on Friday, Oct. 17th, at 7 P.M. for 7.30 P.M.

Westminster Hospital.—The annual dinner of past and present students will take place at Grosvenor House, Park-lane, W., at 7.30 P.M., on Oct. 1st. Dr. S. E. Dore will preside. Winter session commences Oct. 1st. An inaugural address on "The Medical School, the University, and the State" will be given in the Board Room at the Hospital at 3 P.M. by the Vice-Chancellor of the University of London, Rev. J. Scott Lidgett.

Pharmaceutical Society of Great Britain.—The School of Pharmacy will be opened on Oct. 1st at 3 P.M. The inaugural sessional address will be given by Mr. Arthur W. Hill, F.R.S., the Director of the Royal Botanic Gardens, Kew.

Royal Dental Hospital, School of Dental Surgery.—The prize distribution and conversazione will be held at the Hospital in Leicester-square, at 8 P.M., on Thursday, Oct. 2nd. Sir John Rose Bradford, F.R.S., will preside.

PRESENTATION.—Dr. M. I. Finucane, surgeon and medical officer to the A Division of the Metropolitan Police for 17 years, was presented on Sept. 10th with a silver cigar and cigarette box by the officers and men of the division.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. T. L. Cleave is transferred to the permanent list.

The following appointments are notified: Surg. Comdrs. J. Kirker to *President* and to *Hermes;* J. C. Kelly to *Victory*, for R.N. Barracks; L. S. Goss to *Erebus*, and E. B. Kelley to *Valiant*. Surg. Lt.-Comdr. S. G. Weldon to *Champion*. Surg. Lts. W. C. Sloan to *Kellett*, and F. W. Gayford to *Royal Sovereign*. Surg. Lt. (D.) T. G. A'C. Emberson to *Royal Sovereign*.

ROYAL ARMY MEDICAL CORPS.

ARMY DENTAL CORPS.

Capts. A. Williams and S. A. McCormack to be Majs.

ARMY RESERVE OF OFFICERS.

Capt. J. A. Charles, from Sup. Res. of Off., to be Capt.

ROYAL AIR FORCE.

M. T. O'Reilly is granted a short service commission as a Flying Officer for three years on the active list.

A. W. Comber is granted a temporary commission as a Flight Lt.

Flight Lt. G. T. O'Brien is transferred to the Reserve, Class D (ii).

Dental Branch.—Flight Lt. W. D. Guyler (temp. Capt., General List, Army, Dental Surgeon) is granted a non-permanent commission as a Flight Lt.

INDIAN MEDICAL SERVICE.

Lt.-Col. P. L. O'Neill to be Col.

Lt.-Col. S. M. Hepworth retires.

COLONIAL MEDICAL SERVICES.

Dr. R. Briercliffe, Deputy Director of Health, Palestine, has been promoted to Director of Medical and Sanitary Services, Ceylon.

The following new appointments have been made: Dr. F. O. Driscoll, Medical Officer, Malay States; Dr. R. G. Mayer and Dr. R. Pilot, Medical Officers, Mauritius; Dr. K. Knowles, Medical Officer, Trinidad; Dr. C. Holmes, Dr. C. R. C. Rainsford, and Dr. J. R. C. Spicer, Medical Officers, Uganda; Dr. T. C. Findlay, Medical Officer, Zanzibar.

West African Medical Staff: Dr. J. Barclay and Dr. J. Caplan, Medical Officers.

LIVERPOOL ROYAL INFIRMARY.—During 1929, the annual report shows, this hospital worked at high pressure. The 6752 new in-patients were an increase of 510 over those of the preceding year, and 50 per cent. greater than seven years ago; the average stay was 15·49 days. There were 367 births in the maternity ward, as compared with 297 in 1928. The 36,781 new out-patients were an increase of 3293. There were 3363 operations on in-patients and 3750 on out-patients. In view of a waiting-list exceeding 800, it has been decided to proceed with the building of the second portion of the new nurses' home which will release the site of the present home for additional hospital accommodation. A further £25,000 is needed to complete this second instalment.

RADIUM AT BRADFORD ROYAL INFIRMARY.—Last year 3845 in-patients were treated, an increase of 113. Their average stay was 22·5 days, and the death-rate 7·2 per cent. The average cost per patient was £8 16*s.* 11*d.*, and of each occupied bed £143 6*s.* 8*d.*, figures slightly in excess of the preceding year. There were 4686 new out-patients, an increase of 305. The casualty patients were 7953, of whom 1736 became in-patients. The report of Dr. Chester-Williams on the work of the radium therapy department, which was opened in March, 1929, states that work began with 500 mg. and 12 beds, but upon the delivery of a further 225 mg. in the autumn four more beds were made available. The long waiting-list of urgent cases makes a larger supply of radium a growing necessity. The shortness of time since the department was opened admits of no claims of cure, "but it is satisfactory to note that many patients who had inoperable cancer when admitted are apparently free from disease to-day and are leading normal lives." The total number of patients treated was 243.

MODERN TECHNIQUE IN TREATMENT

A Series of Special Articles, contributed by invitation.

CCCVII.

TREATMENT OF CASES OF ABORTION.

PART II.*

Habitual Abortion.

IN some women miscarriage is the almost invariable termination of pregnancy; in some cases the cause is clear, but in many no satisfactory explanation can be found. Syphilis, chronic renal disease, and toxæmia have long been known as causes of habitual abortion, and as these conditions can be recognised by examination of the blood or urine they can easily be detected or excluded in investigating a case. If syphilis is the cause, treatment for this disease of both parents after miscarriage has occurred will almost certainly prevent others, and even if treatment of a syphilitic woman is undertaken early in her pregnancy there is a good prospect of a living healthy child being born. Chronic renal disease which is bad enough to cause threatened abortion in early pregnancy is so dangerous to the mother's life that no attempt should be made to save the pregnancy, and in cases of toxæmia, unless there is very rapid improvement from treatment, it is better that abortion should occur. Both these conditions occurring in early pregnancy are definite indications for inducing abortion. Retroversion of the uterus is considered by some to be a common cause of abortion, but in my opinion there is no solid foundation for this view; it is very common to find the uterus retroverted early in pregnancy, but in the great majority of these cases no harm is done by the position, and the uterus comes forward at or before the tenth week without disturbance. If it becomes incarcerated there is some fear of miscarriage occurring, but even in these cases the uterus usually comes forward and the pregnancy continues. I have seen more than one miscarriage occur after reposition of a retroverted uterus early in pregnancy, and I am sure that the dangers of miscarriage are greatly increased by these unnecessary manipulations. Over-exertion, shocks, both physical and mental, long tiring motor or train journeys undoubtedly may cause miscarriage; there are some women who can take hard and tiring exercise, including tennis and riding, without disturbing pregnancy, while at the other end of the scale some are unable to get out of bed without running great risk of starting a miscarriage. Between these two extremes every grade is found, so that one woman who has had miscarriages may be able to avoid others simply by doing less, while another, if she is peculiarly susceptible to miscarriages, may have to remain in bed for several months or even during the whole of the pregnancy in order to save it.

In recent years the importance of the internal secretion of the corpus luteum of pregnancy in preventing detachment of the ovum from the uterus has been established by animal experiments, and considerable success has been obtained in the treatment of women who have had frequent miscarriages. If such women are given two or three grains of extract of corpus luteum three times a day during pregnancy a greatly increased proportion of their pregnancies will be saved. Another cause of habitual abortion is faulty or arrested development of the ovum. It is not uncommon in dealing with an abortion as late as 12 or 14 weeks to find no trace of a fœtus, which by that time should be three or four inches in length, and instead, all that is found is an ovum perhaps the size of a hazel-nut, embedded at some point in the decidua. In other cases the pregnancy develops apparently quite normally to the fifth or sixth month, when the movements of the child begin to get less and less vigorous, the uterus does not increase at its normal rate, the heart sounds of the child become more difficult to hear, and finally cannot be heard at all; later the uterus actually becomes smaller and there are evident signs that the child is dead. After death in utero the ovum may be retained for several weeks before labour starts. This type of case suggests gradual failure of the blood-supply of the placental site to increase to meet the requirements of the developing child, which gradually becomes more and more feeble until it dies of starvation. In the first type of case the mother is often a woman who has had several children and is reaching the time of the menopause; in the second she has commonly had one normal child, or perhaps all her pregnancies have ended in the death of the child in utero between the fifth and seventh months. Some of the women of the second type show the clinical signs of thyroid deficiency, and in other cases it may be detected by their low metabolic index. Treatment by thyroid extract should be undertaken in these cases, and already several successful results have followed its administration in women who have had more than one pregnancy that has been terminated by gradual failure of the child in utero.

ADVICE ON THE AVOIDANCE OF ABORTION.

In advising women during pregnancy who are apparently normal with a view to avoiding miscarriages, it is important to remember that some women are unable to lead an ordinary life without bringing on miscarriage, and that in many any tiring or strenuous exercise will upset pregnancy. When a woman is in her first pregnancy it is impossible to know whether she is liable to miscarriage or not, so that the only safe course is to advise a primigravida to take reasonable care and to avoid hard exercise and getting overtired. If she goes through her first pregnancy without any disturbance, she can on another occasion lead an ordinary life with very little risk of doing any harm. If a woman has a miscarriage in her first pregnancy she should certainly take special precautions against over-exertion; games like tennis and golf, and riding should be avoided.

Illegal Abortion.

Often when a doctor is called in to treat a woman who is having or has had an abortion, he may suspect that its cause has not been natural, and he may indeed be virtually certain that attempts have been made to procure illegal abortion. If any intra-uterine manipulation has been done there is always grave risk of infection, so that a doctor may find himself in the position of treating a woman for abortion who may die from the effects of infection introduced before he saw her, and be faced with the responsibility of a coroner's inquest and possibly the suspicion that he himself has procured the abortion.

If a doctor is called in to treat an abortion it is, of course, his duty to save the woman as far as possible from danger, but if he suspects or has reason to know that abortion has been procured by any means, he should certainly call in another doctor in consultation. If this is not done and the patient dies there may be no evidence whatever except his word to disprove an

* Part I. appeared last week.

accusation against him of illegal practice, whereas the support of another doctor may help to save him from disagreeable suspicion. If the patient recovers from an abortion which the doctor virtually knows has been induced the general opinion is that there is no need for him to make a statement to the police; but if the patient should die and he is in any way suspicious of the cause of the abortion, it is his duty to report the matter to the coroner. He should on no account sign the death certificate.

J. P. HEDLEY, F.R.C.S.Eng.,
Obstetric Physician to St. Thomas's Hospital.

SPECIAL ARTICLES

SOME IMPRESSIONS OF THE INTERNATIONAL CONFERENCE ON SILICOSIS,

HELD AT JOHANNESBURG, AUGUST, 1930.

BY A. J. HALL, M.D., F.R.C.P.,
PROFESSOR OF MEDICINE IN THE UNIVERSITY OF SHEFFIELD.

SOUTH AFRICA was the first country to deal systematically with the problem of occupational silicosis. In less than 20 years after gold-mining had begun on the Witwatersrand disability amongst the miners on account of respiratory trouble was so widespread and so serious that measures for prevention and compensation became imperative. The burden was shouldered in the large and broad spirit which is so characteristic of that great and progressive country.

Organisation.

During the last 25 to 30 years the medical organisation has been gradually extended and improved, methods of prevention have been increased and modified, compensation has been adjusted by successive Acts of Parliament. It was therefore natural that Johannesburg, the centre of the gold-mining industry, should be chosen as the place for the holding of the first International Conference on Silicosis. As one of the pilgrims to that Mecca I propose to give a brief account of the conference and its results.

The actual number of delegates was necessarily small, yet in spite of the long journey and the comparatively special nature of the subject under consideration, there were representatives not only from all parts of Europe but also from the United States, Canada, and Australia—a reminder of the many urgent and important points which still await settlement in almost every land.

The work of organisation had been undertaken by the International Labour Office of the League of Nations at Geneva, in close coöperation with the Chamber of Mines at Johannesburg. It is the first international conference as yet held outside Europe. It was opened on August 13th by the Minister of Posts and Telegraphs, who formerly welcomed the delegates to South Africa. From then onwards it met for two sessions almost daily until August 27th when the resolutions which it had adopted were submitted to a public session.

The general plan was as follows. A few weeks before the date of the conference each delegate was supplied with a series of 25 reports. Each of these had been written by a delegate. Whilst those of the visiting delegates dealt with the occurrence in different industries, distribution and mode of handling of the disease in each country respectively, those written by the South African delegates dealt each with one particular aspect of the subject with which the writer was especially concerned and indicated in detail how it was handled in South Africa. These reports, which will appear in the publications of the International Labour Office in due course, formed the basis of the discussions before the conference. The discussions were divided into three groups: (1) preventive, (2) clinical and pathological, and (3) prognosis, compensation, and after-care. Rapporteurs selected from the South African and foreign delegates were appointed for each of these sections, and their reports after full discussion formed the basis of the final resolutions adopted by the Conference.

Work of the Medical Bureau.

Before beginning the discussions, two days were devoted to showing the visiting delegates the methods of working adopted at Johannesburg. The work of the Medical Bureau is carried out under one roof, the Medical Research Institute, a large handsome building standing on a hill at the north side of the city, within easy distance of the station adjoining the hospitals and the medical school. As its name implies, this is primarily a place for medical research of all kinds for which it is fully supplied with well-equipped laboratories. There are spacious animal houses, including stables for 50 horses, used for the preparation of sera of various kinds, with grazing ground alongside.

The pathological laboratories of the Institute deal with the whole of the silicotic work. The clinical and radiological work connected with silicosis is carried out by the Medical Bureau, which has a certain part of the ground floor of the Institute allotted to it for that purpose. This is necessarily a very large organisation. When one takes into account that every white miner has to pass an initial physical examination of fitness before being allowed to apply for work in the industry, and that when at work he must present himself for re-examination at intervals of six months, the actual number of examinations of such individuals amounts to over 30,000 annually. These examinations at the Medical Bureau apply only to the miners of European extraction, and do not include any work in connexion with the much larger number of non-European miners and native labourers, amounting to about 200,000, for whom a separate and more simple form of supervision is provided. Over this work the Bureau exercises a general supervision only. It is unnecessary to go into details of the exact procedure of all examinations at the Medical Bureau. Suffice to say, that it consists of seven whole-time clinicians, together with a radiologist, pathologists, and the requisite clerical staff, photographers, &c.

Each morning is devoted entirely to the examinations of the day. Each candidate, after full details of his history have been taken, is photographed for identity purposes. He is then X rayed and undergoes a full clinical examination by one of the clinicians, particularly as regards respiratory functions. Should there be anything in the least doubtful in this respect he is sent to another clinician for a second independent examination. These examinations are all completed by midday and after lunch the seven clinicians meet

to consider all the cases. The proceedings must be unique amongst medical doings, and are certainly most impressive to a looker-on.

A CLINICAL TEAM.

The clinicians, under the presidency of the chief medical officer, sit around a large circular table in the centre of which is a revolving radiogram stand, with two faces. As each candidate's number is read out by the President from his list an attendant places the corresponding X ray film of that morning on one side of the stand, and the last previously taken film on the other side. At the same time the clinician who has examined the man in the morning reads out briefly his weight, his chest measurements, and any findings in the chest, &c. The radiogram stand is revolved so that all can see the films. Opinions are freely expressed by all before a final decision is reached. In most cases the decision is speedy and unanimous, and indeed the rapidity with which the whole proceedings are carried out is at the outset somewhat bewildering to the observer seeing it for the first time. It soon becomes clear, however, that this rapidity, an essential in dealing with such large numbers, has been attained not by any sacrifice of thoroughness or accuracy, but merely by an excellent organisation on the part of a team working together day by day and knowing exactly what is the share of each.

As in other well-organised undertakings, the bulk of the work has already been done before the sitting of the Bureau, which has only to intervene in any case presenting unusual or obscure phenomena. We lookers-on were satisfied that the Bureau carried out its functions on the whole thoroughly and efficiently, and that there was ample provision for the careful investigation of doubtful cases, which provision was fully made use of. Thus any case which presents difficulties and calls forth real differences of opinion is sent to the ward connected with the Bureau for special further observation.

PATHOLOGICAL MATERIAL.

So much for the clinical side of the work, as regards the pathological side it is carried out in the laboratories of the Institute. Here the material is necessarily also vast in amount and offers an unrivalled field for observation. The routine duties in connexion with compensation cases necessarily take up the greater part of the time of the staff, but a considerable amount of research has been and is being carried out by the pathologists, some of which is of evident promise. When, however, one considers the many important problems connected with this subject which are calling urgently for solution, and the immense amount of material here available for almost any line of research, one cannot help feeling that more time and money could be well spent upon providing active research workers quite free from all routine duties.

Mention must also be made of that important side of the Bureau—namely, the radiographic. For the purely technical details reference may be made to the coming publication by the International Labour Office of the reports dealing with the subject. Actually, for the information of the delegates, a wonderful exhibition of films had been staged. This showed every phase of silicosis with all its modifications, and its combination with tuberculosis in all degrees and forms. Many series showed radiograms taken at regular periodic intervals extending over a number of years, in which the actual development and course of the disease were clearly demonstrable. In some 400 cases of silicosis the Bureau has been able thus to compare together the clinical, radiological, and post-mortem findings, and these composite results have added greatly to our knowledge. Further work on these lines is being carried on.

NATIVE WORKERS.

It seems at first sight a little strange that this close medical supervision of all the miners of European extraction (that is, the white men) should not be equally necessary in the case of the non-European or native workers underground, who relatively number about 20 to 1. For this there is a good explanation. The South African records since the Bureau was established show clearly that Rand miners under existing conditions are practically exempt from recognisable silicosis for the first two or three years of exposure underground. Even up to six or seven years the incidence is only very small. The native worker rarely remains in the mines for more than a few months, perhaps 9 or 12, after which he returns to his kraal and his wife, having earned enough money to set him up. He may never return to the mine, or he may do so for another short period followed by another interval of home life. The result is that comparatively few of the natives are disabled by silicosis, and the stringent medical machinery adopted in the case of long-time European miners is not required.

As a matter of fact, however, there is a considerable medical control over the native workers. Each man undergoes two general physical examinations before being allowed to enter the mines, particular attention being given to the question of pulmonary tuberculosis. Throughout his period of work also, a careful watch is kept for any suspicion of this. The native population is extremely susceptible to tuberculosis, and tuberculosis is gradually being recognised as the factor of greatest importance in the problem of silicosis as a disabling disease. After the visiting delegates had been shown all the details of this great machinery for coping with the effects of silica dust amongst the Rand miners, the actual Conference began its sittings.

The Discussions.

The printed reports referred to above were taken as read. Their discussion gave rise not only to many interesting points, contributed by the delegates from overseas with experience of the disease as it presents itself in industries with working conditions entirely different from those in the South African mines, but it also elicited a great amount of first-hand information from the South African delegates in elaboration of points about which their reports had been necessarily incomplete or difficult to understand.

As was stated above, these discussions were divided into three large divisions :—

1. Preventive Measures.

Here as elsewhere it became evident from the outset that accurate knowledge of almost every detail is still wanting. It was agreed that the disease which under this heading it is sought to prevent is that which arises from the inhalation of free silica (SiO_2), as distinct from silica in chemical combination with other substances.

It becomes noticeable after widely differing periods of exposure to siliceous dust depending apparently upon : (*a*) the amount of dust inhaled ; (*b*) the percentage of silica contained therein ; (*c*) the size-frequency (or fineness) of the particles inhaled ; (*d*) the nature and sort of such other substances (including vapours and gases) as may be inhaled simultaneously, or otherwise ; (*e*) the powers of resistance of the individual concerned ; and (*f*) the presence or absence of a complication by an infective process.

Whilst the importance of each and all these factors was fully recognised, this section of the discussions spent itself chiefly upon the first three. As regards the question of dust measurements, it was felt that our lack of accurate knowledge or of any agreed standard of measurement calls for immediate research, towards which the assistance of the pure physicist should be sought. Until some standard is set up applicable to all industries in which there is exposure to free silica dust, it is impossible to form any accurate estimate of the relative risk of such industries or to formulate the best methods of coping with each in particular. The Conference expressed the strong hope that the settling of such a universal standard of dust measurement might be attempted immediately, and felt that the place best suited for such research would be in the Witwatersrand mines of South Africa. When such a standard means of measuring dust is fixed, a complete world survey of dusty industries of all kinds should follow at an early date.

Much discussion took place as to the relative values of ventilation, general and localised, control by means of water or other solutions, and the use of masks of various kinds. It was pointed out that no single one of these methods can be equally well applied to every form of industry involving exposure to silica dust. Measures which may prove efficacious in the case of a man working at a bench or at a wheel would be quite unfitted for one working underground at the rock face and vice versa. Water, whilst allaying the dust, necessarily increases the humidity, often to an extent which may render the risk of a concomitant bacillary infection more serious. Indeed, the factors involved in all such preventive measures are so many and their interaction is so complex that great caution is necessary before deciding upon the best method in any particular industry. Under any circumstances the importance of general and localised ventilation was urged as one of the best hygienic measures in dusty industries.

Besides these preventive measures dealing with the noxious cause, others of great importance concern the resistance of the worker. In this respect emphasis was laid on the necessity of ensuring that a certain standard of physique should be generally required for all workers entering industries in which the risk of exposure to silica dust is great. This can be met to some extent by an initial medical examination such as already exists in South Africa and in some other places. Further, as experience shows that the onset of silicosis bears a definite relation to length of exposure to dust, periodic medical examinations of those engaged in the industries are essential. Such examinations should be carried out by medical experts who should have at their disposal every facility for conducting the examination. In effect this means that the examinations must be as full and complete as modern medical knowledge can offer.

2. Medical Aspects.

This division of the subject gave rise to prolonged and interesting discussions. On the clinical side general agreement was reached that the earliest recognisable stage of silicosis could be reasonably fixed by the combination of history, clinical signs, and radiographic appearances. The first recognisable stage of silicosis has been called by the South African Medical Bureau "the anteprimary stage," and as such is recognised in their legislature dealing with the subject. The Conference, whilst fully realising how and why this term arose in South Africa, felt that it would be a misfortune to perpetuate it in other countries, and suggested calling the three stages first, second, and third respectively, in order to avoid confusion.

DEFINITION OF THREE STAGES.

The first stage of silicosis corresponds with the South African anteprimary, the second with their primary, the third with their secondary stage. Tuberculosis may occur with silicosis in any stage. Definitions of each stage based upon the history of employment, clinical features, and radiological findings were laid down, and the importance of due consideration to all three of these data before arriving at a diagnosis was insisted upon. Neither the clinical features, nor the radiological findings alone, nor the two combined are in every case sufficiently characteristic to warrant a definite distinction from other pneumonoconioses, although in some cases and in some stages they may be. These definitions will be found in the report of the Conference to be published shortly.

As regards the pathology of the disease interesting experimental results were shown from prolonged dusting with free silica in animals. From these the Conference feel justified in concluding that "silicosis is a pathological condition of the lungs due to inhalation of silicon dioxide which can be produced experimentally in animals." Further experimental work on these lines is urgently called for, and gives hope of fruitful results in many directions.

MICROSCOPIC CHANGES.

So far the investigations suggest that the microscopic pathological changes which may be produced by the prolonged inhalation of silica dust are: (*a*) The development of a dry bronchiolitis characterised by an accumulation of dust-filled phagocytes in or in relation to the terminal bronchioles with possibly some desquamation of their epithelium. (*b*) The accumulation of dust-containing phagocytes about and in the intralymphoid tissue and their transportation through the lymphatics into the tracheobronchial lymph nodes. (N.B.—Up to this point in the process it is considered that the actual disease silicosis is not yet constituted.) (*c*) The gradual development of fibrous tissue within such accumulations of phagocytes and the formation of characteristic nodules of hyaline fibrous tissue. (*d*) Degenerative changes in these foci. (*e*) The hyaline nodules increase in size by extension at their periphery. Coalescence of adjacent nodules takes place and brings about involvement of further areas of the lung. (N.B.—The conditions described under (*c*), (*d*), and (*e*) constitute the disease silicosis.)

MACROSCOPIC CHANGES.

Macroscopically the changes observed in silicosis are:—

(*a*) *In the first stage:* A variable number of palpable pearly-white nodules up to 2 or 3 mm. in diameter on the pleural surface of the lung. On section the cut surface of the lung is studded with pigmented foci, widely scattered, a moderate proportion of which are only just palpable. The tracheo-bronchial lymph nodes are slightly enlarged and deeply pigmented, and may exhibit foci of fibrous induration.

(*b*) *Later stages:* The fibrotic nodules are increased in number, size, and density, and coalescence of these may be found. The portion of the lung between the fibrotic nodules may be emphysematous. The tracheobronchial lymph nodes are still pigmented, may be smaller in size than those seen in the early stages, and are fibrosed.

The above refers to the features produced in silicosis alone, but as is well known the combination of tuberculosis with silicosis may occur at any stage

and modifies the clinical, radiological, and symptomatic picture profoundly. Moreover, there is reason to think that other pulmonary infections may similarly complicate a simple silicotic process and add to its general pathological effect. In this connexion difficulties present themselves. What these exactly are may be made more evident by a short account of the present position in South Africa.

RELATION OF SILICOSIS AND TUBERCLE.

By their existing legislation two distinct groups of cases are compensated: (1) those suffering from silicosis, and (2) those suffering from tuberculosis with silicosis. For this purpose tuberculosis is defined by the Act and the definition makes it clear that the tuberculosis must be recognisable as such. These two broad groups exist and the relative disability which they cause is sufficiently different to call for a difference in the amount of compensation.

With the increasing experience of recent years, however, it has been realised that all the cases coming under Group 1 (Silicosis) are not identical either in the extent of disability, radiological findings, or rate of progress.

For purposes of reference, therefore, the Medical Bureau divides Group 1 (Silicosis) into two subgroups: (A) Simple Silicosis, and (B) Infective Silicosis. The latter show relatively greater disability than their physical signs would lead one to expect; radiologically they show the hanging heart, and, on the whole, they get worse more quickly than cases of Type A—although much less rapid and serious in progress than cases of Group 2 (Tuberculosis with Silicosis). It must be clearly understood that cases both of Subgroup A and Subgroup B are classified for compensation purposes as Group 1—to which they obviously belong.

"INFECTIVE SILICOSIS."

As is stated above, in South Africa this group of cases is at present referred to by the Medical Bureau as silicosis of infective type or "infective silicosis." The term is made use of entirely for scientific purposes and without any commitment as to the nature of the accompanying infection. It does not occur in their legislative terminology. The so-called infective element may be different in different cases, or may be multiple in an individual case. There is some evidence obtained from biological experiments, made from the lungs of a certain number of cases of infective type after death, that the particular infective element may have been a latent focus of pre-existing tubercle, which has not shown recognisable features of tuberculosis during life. There is comparatively little evidence as to the occurrence or distribution of such a twofold type of simple silicosis in other countries and in various dusty industries, and it was felt that on this difficult aspect of pathology the available data are not yet sufficient for any dogmatic statement. The Conference recommended that further scientific research into the ætiology, pathology, and diagnosis of silicosis should be undertaken on an international basis at an early date with especial reference to this point.

As regards pneumonoconioses other than those coming under the definition of silicosis, there was considerable discussion but no very definite conclusions were arrived at, and it was felt that this subject also calls for further investigations.

Reports on the radiographic methods in use in South Africa and Australia are attached as appendices to the reports to which reference may be made for details. In this connexion the Conference thought it desirable to draw up a terminology for the classification of radiograms, which although not presenting appearances corresponding with those accepted as recognisable silicosis yet present linear radiating shadows of greater or less extent beyond normal. In South Africa these have hitherto been classified as radiograms showing varying degrees of fibrosis. It was suggested that it would be better to classify these in terms of shadows—as slight, moderate, or well marked increase of linear radiations, rather than in terms of fibrosis which they may or may not represent.

3. Prognosis and Compensation.

On prognosis the evidence as regards different countries and various industries was somewhat conflicting. On the whole, the hope that early removal from the industry in the first stage of silicosis would necessarily arrest the progress of the disease has not been realised, and it is evident that when a worker has reached the stage of recognisable silicosis he has a definite pathological condition which may or may not progress unfavourably according to various accompanying circumstances, the exact nature of which is obscure. There is also some evidence that a certain proportion of workers suffering from simple silicosis may continue in the industry without any greater increase in progress of the disease than occurs in those leaving it. On these points further information is wanting, and it is possible that fuller knowledge of various industries would show considerable variations in results.

The prognosis in cases of declared tuberculosis with silicosis is always serious. It is worse (*a*) when the tuberculous infection occurs at the outset of silicosis, (*b*) in younger than in older subjects, and (*c*) than in cases of tuberculosis alone.

Compensation and after-care were only dealt with from their medical aspects, and the following conclusions were arrived at: (*a*) Silicosis, complicated or not by tuberculosis, constitutes an occupational disease which may involve reduction of working capacity. (*b*) The determination of disability calls for expert medical examination at which account must be taken of the clinical and functional condition as a whole. (*c*) Seeing the very close and serious connexions between tuberculosis and silicosis, compulsory removal from the industry should be enforced in all cases of declared tuberculosis. (*d*) In those countries where legislation provides for compulsory removal from occupations involving exposure to silica dust of workers affected by silicosis, it should not necessarily be applied to workers who have been in the same industry for a period of not less than 15 years and have reached the age of 45 years.

As regards after-care the provision of sanatoria was approved, and hopes were expressed that further attempts might be made to solve the difficult problem of rehabilitation.

Conclusion.

Although the Conference cannot be said to have made any material addition to pre-existing knowledge, yet it has in many ways served a useful purpose. By collecting together all the available information about dust diseases from all parts of the world, it has shown not only the number but also the position of the gaps in our knowledge of the subject, and so given valuable indications for future lines of research. It has enabled certain standards to be agreed upon, by which future work on this subject may be comparable in whatever country or industry it is carried on. Finally, it has emphasised the urgent necessity for further experimental investigations into almost every aspect of the problem.

THE MEDICAL REGISTER:

UNTRACEABLE PRACTITIONERS IN 1930.

WE are requested by the Registrar of the General Medical Council to publish the following list of medical practitioners who have not replied to his inquiries as to the accuracy of their addresses. It is possible that some of the undermentioned practitioners may have communicated with the Council since the list was drawn up. Anyone, wherever resident, who finds his or her name included in this list should communicate immediately with the Registrar, 44, Hallam-street, Portland-place, London, W. 1, otherwise the name will be omitted from the next issue of the Medical Register. Those marked "(S)" should communicate direct with the Registrar of the Scottish Branch Council, 2, Queen-street, Edinburgh.

BUCHAREST.

(FROM OUR OWN CORRESPONDENT.)

REORGANISATION OF THE MEDICAL PROFESSION.

THE Rumanian Chamber of Deputies, by 133 votes to 7, has passed the new Public Health Bill. The details fill a bulky volume, but the principal provisions may be summarised as follows:—

For the control of medical practice a college of physicians (*Colegiul medicilor*) will be established and only members of this college will be allowed to practise medicine in Rumania. A physician must not take part in any form of commerce, either directly or indirectly, nor must he have any occupation prejudicial to the prestige of the profession. Th college will have one branch in each county and th central board of directors at Bucharest will be const tuted from the presidents of the county council Physicians are forbidden to use any means of attrac ing patients which may lower their profession in th eyes of the public, but the college has the right t require the public prosecutor to take action again anyone who carries on medical practice illegally, an also against anyone who prepares and sells dru without medical prescription. For discipline with the profession, the first tribunal will be the count council of the college. A practitioner may b defended by one of his colleagues, or by a solicito The sittings of the disciplinary council are publ and their decision must be in writing. The cou

of appeal consists of one judge of the Bucharest High Court of Justice, and four doctors appointed by the board of directors of the college. The penalties are as follows: (1) remonstrance; (2) remonstrance and suspension of eligibility for election to the county council for one to three years; (3) temporary suspension of right to practise; (4) removal from the register of the college.

THE PUBLIC MEDICAL SERVICES.

The Act distinguishes five groups of doctors in the public service, according to whether they are concerned with hygiene, healing, laboratory work, administration in cities and parishes, or forensic medicine. Specialists in any branch of medicine must produce evidence of having studied their branch for at least four years after graduation. The law recognises as specialists those who, before its proclamation, were university professors, lecturers, assistants, or senior hospital physicians, or worked as secondary doctors at a special section of a recognised hospital. Private doctors will only be recognised as specialists if they can supply documentary evidence of having worked in their specialty for at least five years.

In the public service the following ranks are established: junior physician, titular physician, chief physician-in-chief, principal physician, inspector-general physician, and consulting physician. As a rule, everyone must begin his public career as a junior physician, and must spend two years in this capacity. If by then he is deemed unworthy of promotion he remains in the same rank for a further year, and if he still does not deserve advancement he must leave the public service for ever. In exceptional cases a man may join the service as titular physician or physician-in-chief if he has served in a private hospital for two years and four years respectively and has especially good qualifications. Advancement is not a certainty in every case, but takes places according to merit. One must, however, spend at least two years as junior and four years as titular physician. The rank of inspector-general is reserved for the most prominent doctors and appointment is subject to the recommendation of a special commission. Their total number cannot exceed 30 in the whole country. If an inspector-general has shown a particularly useful and conscientious activity he receives on retirement the title of *medic consilier sanitar*. The new law considerably raised the grades. The old law knew four grades only, each rise bringing a 15 per cent. rise of the salary. The new law is more liberal and provides five grades, each with 25 per cent. rise, and the total increase of 125 per cent., together with several additional sources of incomes, ensures a very comfortable livelihood. At the age of 60 every physician may be pensioned at the suggestion of the administrative commission. At 62 all must retire without regard to years of service.

DENTISTRY AND OTHER BRANCHES.

The new law definitely settles the troublesome question of dental practice by declaring that dentistry can be carried on by duly qualified doctors or dental technicians who have specialised in stomatology. Those dental technicians who gained their right to practise before 1923 may continue their work without disturbance. Those whose licence was not recognised by the revision in 1924, if over 35 years of age, will have to pass qualifying examinations in December, 1930, while those under 42 will have to attend a regular course, lasting one year, in dental technique and pass the final examination. Only those technicians are justified in applying for admission to the courses who before 1923 had already eight years' practice (two years as apprentices and six years as assistants in laboratories). Those who have passed matriculation examination in a secondary school and attended some foreign high school for dentistry, and obtained a diploma after four years' study, may carry on dental practice in Rumania without further notice. Dental technicians, and also dental surgeons, are not allowed more than one consulting room.

Diathermy, quartz-light, and X ray apparatus may be owned and used by qualified doctors only. Likewise electrolysis and electro-cauterisation should be applied by physicians, and this exclusively medical work must not be done by barbers, masseurs, manicurists, chiropodists, or cosmetic institutes.

The new law puts a stop to brothels and all undertakings connected with the keeping of prostitutes. Henceforth licensed women will have to present themselves twice weekly for medical examination—in towns and cities at the venereal dispensaries, in small towns and villages by the parish doctors.

MENTAL HEALTH IN 1929.

REPORT OF THE BOARD OF CONTROL.

Mental Disorders.

ACCORDING to the sixteenth annual report[1] of the Board of Control there were at the opening of the present year 142,387 notified insane persons under care in England and Wales. This was an increase of only 1307 on the preceding year—about half the average increase—but the Board do not feel that this low figure reflects any real diminution in the incidence of mental disease. It is mainly due to a high death-rate—8·04 per cent.—and also, to some extent, to the increasing shortage of beds, producing a tendency to retain manageable cases in poor-law infirmaries. The margin of accommodation is perilously small, and causes the Board considerable anxiety. They are, however, happy to record that the visiting committees are showing themselves alive to the situation, and that many important extensions were approved during 1929. Brookwood, Glamorgan, Hanwell, and Stafford are building admission hospitals, and Brighton is purchasing a site for one. Banstead, Glamorgan, Long Grove, and Plymouth are building nurses' homes and Barnsley Hall, Bracebridge, Norwich, and Mid-Wales are extending their accommodation.

The total expenditure on the upkeep of county and borough mental hospitals and their patients for the year ending March 31st, 1929, amounted to £7,981,257. The Board no longer publish comparative tables of maintenance rates, for they feel that these are deceptive. They point out that a low maintenance rate is just as likely to spell bad treatment as good management.

HEALTH AND RECOVERY-RATES.

The total number of discharges during the year was 10,497, of which 6997 were discharged as recovered, giving a general recovery-rate for the year of 31·73 per cent., slightly below the average. There were 1216 patients under treatment for tuberculosis at the beginning of 1929; the incidence is highest generally in the northern hospitals, except in Yorkshire, and lowest in the south-eastern counties,

[1] H.M. Stationery Office. Pp. 103. 1*s.* 9*d.*

except Brighton Borough. The figures for the mental hospitals follow closely those for the general population of the areas. During the year the incidence-rate rose 0·5 per cent., and for the first time, the male exceeded the female notifications. The increase seems to have followed the wave of influenza in the spring. In spite of the number of notifications, there were only 1209 tuberculous patients at the end of the year. There was a reduction of about 45 per cent. in cases of the enteric group, and a slight decrease in dysentery. Exhaustive searches are made for the source of these outbreaks but, as the report points out, hospitals not yet provided with laboratory facilities are at a great disadvantage in this respect. There was a considerable increase in the number of cases of erysipelas, principally among women.

Of the total of 1730 patients admitted to licensed houses during the year 43·2 per cent. were voluntary admissions, while 699 voluntary and 610 certified patients were admitted to registered hospitals. In poor-law institutions there were 15,557 certified patients on the first day of the year, but this, of course, is by no means the total of mental cases in these institutions. So far, only one visiting committee has made arrangements for suitable mental patients to be received in a poor-law institution. The Board deprecate the practice of some areas whereby all patients with mental symptoms who need assistance from the rates are sent in the first place to observation wards, which are inadequately fitted and staffed for mental treatment. The report quotes two cases illustrating the dangers of delay in securing effective hospital treatment, and urges that all such cases should be sent direct to a mental hospital.

Mental Deficiency.

It is now possible to secure continuity of treatment and care for the mentally defective by dealing with them as mentally disordered and not as destitute persons. The old confusion is by no means yet cleared away, but the Board hopes to see better things before long. On the subject of adapting poor-law institutions for mental defectives the report makes three comments:—

(1) A few of the better institutions could, they think, be adapted at reasonable cost and might serve as the nuclei of colonies if sufficient land could be acquired; but most of these will be needed for other purposes.

(2) A number of institutions could be adapted for one sex only. The Board recommend that these should be used for the older lower-grade cases who do not appreciate their surroundings, and can only be employed in simple domestic work. This institution should, however, be adequately staffed and should be ancillary to the main colony in the area.

(3) Young, trainable, and employable defectives should only be kept in a poor-law institution as a temporary measure while the colony is being built.

Even if it were possible to use all the beds in poor-law institutions hitherto occupied by defectives, roughly 30,000 cases, mostly young and trainable, would still lack accommodation. Hardly a day passes without an appeal from some local authority for accommodation for an urgent case, and the Board has to reply that no vacancies exist. The number of beds provided by local authorities increased by 1376 during 1929. The report gives a list of authorities who have made some provision, and is able to say that an increasing number of authorities are realising the urgency of the problem, although the provision is still far short of the requirements. There has been an increase in hostel accommodation for mentally defective men and women who are able to be partly self-supporting outside an institution. Hostel treatment provides help and guidance with remunerative daily work, and leads to the possibility of licence or the guardianship of carefully chosen employers.

STERILISATION.

The report discusses the problem of the marriage and sterilisation of defectives. The Board believe in the education of the public as to the nature and needs of defectives who remain at large, and in careful guardianship. They think that many disastrous marriages might be prevented if the local authorities were made guardians and if defectives on licence were visited regularly by trained visitors. They still urge the prohibition of the marriage of defectives under statutory care. While maintaining their view that sterilisation will not solve the problems of mental defect and will do little to alter its incidence, they admit that there are cases in which it might be advantageous and that, if the claims of its advocates are often exaggerated, the condemnation of its opponents rests on an equally unsubstantial foundation.

ASCERTAINMENT.

The increase in ascertainment has continued; at the end of last year 71,439 defectives had been reported to the local authorities, and the ratio per 1000 had risen during the year from 1·69 to 1·8. The returns, however, still vary in different areas from 5·82 to 0·18 per 1000 of the population. The Board confidently expect a large increase in 1930. The Board urge the importance of employing specially trained medical men to make the survey; in these days it is most important to distinguish between those who are unemployed because of their mental condition and those who are capable of work if opportunity offers. For the improvement of ascertainment the Board suggest the following measures:—

(1) Closer coöperation between the various committees of the county and borough councils.

(2) Closer coöperation between the statutory committees for the care of defectives, the managers of Home Office schools and reformatories, the prison authorities, and the remand homes.

(3) Closer coöperation with voluntary and charitable homes and societies.

(4) The appointment of trained officers to carry out the duties of ascertainment and supervision and to develop and supervise guardianship.

(5) The appointment by the local authorities of medical officers with special knowledge and experience of mental defectives.

SUPERVISION.

There were 22,706 cases under statutory supervision at the beginning of this year, and 20,032 under voluntary supervision. This is a gratifying increase, but local authorities still vary extraordinarily in their activities in this direction. The Board urge the appointment of trained officers, the provision of occupational and industrial centres, and of home training, and the full use of carefully selected voluntary visitors in order to render supervision really efficacious.

There are now 161 occupational and industrial centres, which are doing very good work, but the Board think that guardianship as a means of care is not increasing as rapidly as is desirable.

After a review of the results of discharge and licence during the past five years they conclude that discharge has been too often fortuitous instead of dependent on the ability and temperament of the defective and his home circumstances. Most of the successful cases were only discharged after a graduated process of re-education and stabilisation ending in prolonged periods of licence. The growing practice of sending out defectives on long licence seems to be satisfactory, and the Board deprecate any pressure to discharge these cases. It cannot be argued that because defectives have done well under licence they

will do equally well on discharge; they need the forbearance and supervision available on licence, and complete liberty in a competitive labour market often means social disaster.

Varia.

As usual, the details of research work in mental hospitals will be set out in the second part of the report. There has been a welcome increase on previous years, including two reports from mental deficiency institutions. A research chemist has been appointed to the staff of Cardiff City Mental Hospital. Special observations are still being made on cases of encephalitis lethargica. The number under care has fallen from 260 in 1927 to 182 in 1929, but these figures do not represent the whole toll of the disease.

Good progress has been made during the year in the provision of nurses' homes, a policy which the Board regard as an essential part of the modernisation of mental hospitals. Modern nursing demands an educated nurse, and no pensions scheme or any advantage of the kind will make up for unsatisfactory conditions of living. The Board also remark on the high level of qualification which has been demanded of medical officers appointed during the year. There is, however, a great shortage of doctors properly trained in mental deficiency. The Board do not want to add to the already alarming number of special diplomas, but they would like to see courses of post-graduate training available at one or two colonies within easy reach of a teaching hospital.

The report comments on the foreign study tours organised by the Royal Medico-Psychological Association, and expresses a hope that the League of Nations health organisation—which has hitherto ignored the mental hospital service in this respect—will in time recognise the importance of interchange in the sphere of mental disorder.

PUBLIC HEALTH SERVICES

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1929 statistics of five districts which serve in varying degrees as dormitories of London:—

Name of district and estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Willesden U.D. .. (177,973)	16·5	11·7	1·01	1·35	2·4	1·9	61/32	34	4·1
Tottenham U.D. .. (155,000)	16·5	11·9	0·91	1·26	3·4	1·9	63/28	25	1·6
Ford B. .. (112,489)†	15·6	9·7	0·71	1·24	2·0	2·0	49/27	20	4·0
Ealing B. .. (104,000)	14·7	12·4*	0·96	1·44	2·8	2·3	48/22	—	2·0
Hornsey B. . (88,450)	13·8	12·7	0·82	1·62	3·0	1·6	55/30	21	4·1

Stillbirths per 100 live births: Willesden 2·7, Tottenham 3·4, Ford 2·8, Ealing 2·7.

* Standardised rate 11·3.

† After deducting populations of Claybury and West Ham dental hospitals.

Willesden.

Dr. George F. Buchan describes the results of the first six months' work of the Council's clinic for the early diagnosis of cancer up to March 31st, 1930. Of the 52 patients who sought advice, 18 were in need of active treatment for various conditions and 2, including one definite case of cancer, of operative treatment for conditions regarded as forerunners of cancer. The coöperation of the hospitals for treatment has been secured and the press has given wide publicity to the importance of early diagnosis. A coördinated effort is also needed in Willesden to mitigate the results of rheumatic fever, the full benefit of which, however, can only be expected later from the prolongation of working life and the decreased death-rate from heart disease among those attacked. The diphtheria immunisation clinic, established in May, 1927, has come to an end, owing to the lack of parental support. Only two school-children and seven children under 5 years of age attended during 1929. There were 47 notifications of small-pox of the mild type. One death occurred in a man of 63 years from encephalomyelitis, which has aroused medical interest, as this complication has occurred after vaccination, measles, and other diseases. The clinical and pathological details have been published in THE LANCET (1930, i., 566). Nine deaths were attributed to infectious diseases of the nervous system. No deaths from typhoid fever were recorded.

Of the 2714 children born in Willesden, 34·7 per cent. subsequently attended the welfare centres; and the number of births to expectant mothers who attended the antenatal clinic was 564. Under the council's scheme for hospital treatment for children under 5 years, 80 were successfully operated on for tonsils and adenoids and 11 were treated for marasmus with one death. In the endeavour to cope with maternal mortality, the council as from Jan. 1st, 1930, provide sterilised accouchements sets (free, if necessary) and accept responsibility for the fee of a consultant or of an anæsthetist, when needed for a confinement case. Over 4500 mothers attended the three schools for mothers, which had useful programmes of needlework classes and competitions, and lectures, demonstrations, and visits of health interest. Before the war the percentage of verminous school-children discovered at routine inspection was over 20; since the war the figure has come down year by year to 4 in 1929. The scheme for the dental treatment of the elementary school-children is "admittedly incomplete." After an elaborate and complete system of inspection 11,217 out of 15,749 children were found to need treatment, and yet only 2171 received treatment at the dental clinics.

Out of 48 samples of milk examined three were found to contain tubercle bacilli. On two farms tuberculous cows were slaughtered under the order and on the third farm the investigation had negative results.

Tottenham.

Dr. David C. Kirkhope says the outstanding problem is still the housing of poorer families at rents within the compass of their incomes. No subsidised houses were erected during 1929. There were six mild cases of small-pox—the first since 1910. The treasurer's estimate of the population is 168,000. Diphtheria was more prevalent than in 1928—562 cases with 30 deaths (case-fatality 5·3 per cent.). Parents show little disposition to take advantage of immunisation facilities offered. In the endeavour to fill the gap between infancy and school entrance, provision has been made in the next three-years programme for two nursery schools and two nursery

classes. Ionisation continues to give successful results in otorrhœa. Cases are coming up for treatment at an earlier and more amenable stage and "diastolisation" is proving valuable for acute and chronic inflammation in the nose and in thus preventing deafness. An audiometer is to be procured in order to measure accurately the amount of defect and the degree of recovery after treatment. The 32 Tottenham children at the school for the deaf include 19 totally deaf, and it is pointed out that such totally deaf children with normal brain power, whose attendance is regular, should leave school with intelligible speech and useful lip-reading and able to express their thoughts and receive the ideas of others, after starting school life speechless and languageless.

Ilford.

Dr. A. H. G. Burton reports a considerably increased prevalence of diphtheria. There were 305 cases and 16 deaths. The occurrence of 123 cases on the L.C.C. Becontree estate was an illustration of the fact that in these days of carriers good housing does not give immunity. Since November, 1929, 1039 children have been immunised in this neighbourhood. The accommodation at the isolation hospital has been strained and 28 acres of land have been purchased and a layout of the proposed extensions is shown on a plan. The use of antiscarlatinal serum has reduced the duration of stay in hospital. In 1909 the average stay for scarlet fever was 44 days and in 1929 it was 31·3 days. Most cases who receive the serum early can be discharged in three weeks without increased risk of complications or return cases. The school medical service has been extended by the provision of an orthopædic scheme and the appointment of an additional dentist. The open-air school for 100 children began work on Jan. 29th and has already proved its value. The maternity home, opened in 1926, admitted 481 patients and already needs extension. Dr. Burton recommends the provision of a new ward block for difficult emergency cases and a new antenatal clinic also in a separate block. There are six cowsheds on the register. In 1927 Major J. A. Boseley was appointed veterinary inspector for the Milk and Diseases of Animals Acts. During 1925 five cows (two in milk) at the farm attached to a public institution were reported as suspect. Three had advanced tuberculosis and two chronic cough and other signs. All were slaughtered.

Ealing.

Dr. Thomas Orr reports that a scheme is in operation under which every child from birth to school-leaving age will soon receive appropriate treatment for crippling defects. During the year the orthopædic surgeon on his monthly visits to the clinic saw 73 school-children and 87 children under school age. The demand from the parents is so immediate as to necessitate increased accommodation. Operative treatment in hospital, if needed, is provided at Stanmore. The Minister has made Ealing Town Council the supervisory authority under the Midwives Acts and also the authority under the Nursing Homes Registration Act, 1927, thus reversing the action of the Middlesex County Council in refusing to delegate. Dairy premises have been greatly improved and milk in sealed bottles is only allowed to be sold from general stores if it is kept in a cool place. The municipal day nursery has been closed owing to the small number of children seeking admission and the relatively high cost per attendance. The mothers were going out to work and earning 4*s.* to 4*s.* 6*d.* per day, of which they paid 9*d.* for the maintenance of each child at the nursery, leaving the balance of 4*s.* 9*d.* for the average cost of each attendance to be paid out of the rates. It would have been better, Dr. Orr points out, to make a grant to the mother to look after her child at home, but there is no legal power to make such a grant. There is little demand for nursery schools in the borough and the Education Committee admit children between 4 and 5 years of age to infants' departments when this course is desirable. The latest school, now nearing completion, is of the "Derbyshire" open-air type, and two other new schools and a department of similar construction are to follow.

Hornsey.

Dr. R. P. Garrow reports that the new houses were all subsidised—73 houses and 12 flats (private enterprise) and 33 municipal flats. Thirty families including 148 individuals, were moved from overcrowded houses during the year and 33 more were to be moved in April, 1930. The inspectors take steps to prevent recurrence of the overcrowding in the vacated houses. The milk consumed in the borough is estimated at half a pint per head of the population per day. Two roundsmen were fined for selling milk in bottles not filled and closed on registered premises. The municipal midwife attended 136 births and earned £200 16*s.* in fees. The mothers took so much advantage of the maternity and child welfare dental sessions that it was not possible to treat children under 5 years. Dr. Garrow thinks many of the school-children show a lack of robust health, pointing to poor feeding in infancy and childhood. Mr. A. J. Friel treated successfully 70 cases of otorrhœa at his clinic. A local orthopædic clinic is to be established in connexion with the Royal National Orthopædic Hospital and its country branch at Stanmore. A Church of England school, which had been placed on the Board of Education List B, has been entirely reconstructed and extended by the generosity of Mr. David Greig, first freeman of Hornsey (1929) and is now well up to modern requirements.

REPORTS OF SCHOOL MEDICAL OFFICERS

—	No. on roll.	Average attendance.	Routine inspection.	Special exams. and reinspections.	Percentage of defects
Liverpool ..	—	—	42,266	61,029	17·2
Kent	75,736	—	24,268	25,814	15·7
Leicestershire ..	38,019	33,851	10,535	8,907	15·3

Liverpool.

Dr. A. A. Mussen reports advance towards the full development of the service; with the opening during the forthcoming year of two day open-air schools and the orthopædic and other clinics, the only outstanding requirement is the extension of the dental scheme. Additional clinics for the treatment of minor ailments including defective vision and dental work are to be opened at an early date, when the facilities as a whole will be distinctly above those provided elsewhere. For tonsils and adenoids there is a special clinic with 12 beds; hæmorrhage occurred in about 7·9 per cent. of the cases, in a few after discharge from the clinic. That there are so few due to the care given to after-treatment at home printed instructions are sent to the parents about the need of rest for three days, and the nurse impresses upon them the need of carrying out instructions faithfully. It seems that these instructions are unheeded in 30 per cent. of the cases; for instance, a boy played in a billiard match on the night after his discharge and, it is said, blamed the clinic for his defeat. Advice as to food is similarly disregarded. In otorrhœa, treatment by zinc ionisation is giving improved hearing and freedom from recurrence more than other methods. Dental facilities are improving with the appointment of an additional dentist. Orthopædic clinics and hospitals are being adequately provided. Ophthalmic work is thoroughly carried out, including the much needed reinspection of those who fail to wear their glasses, and advice to the parents of myopic children about to leave school. Some of the medical staff have carried out an investigation into the hereditary transmission of Leber disease, hereditary optic atrophy, a kind of research

for which school doctors have special advantages. Records of all cases of defective vision are kept, and from these it was found that all the cases of this disease in Liverpool could be traced back to one blind ancestor; transmission followed Mendelian laws, and was not sex-limited as is commonly thought. The onset was earlier than described by Leber. Accommodation for exceptional children, including stammerers, is more nearly adequate in Liverpool than in most other areas; a fine senior M.D. school has just been added. Squint is treated in pre-school children, a most valuable provision, but otherwise hardly any mention is made of this age-group.

Kent.

Dr. Alfred Greenwood reports a year of smooth working, with an increase in the total number of examinations. There is little mention of extended facilities for treatment or accommodation for exceptional children, and there is still no open-air school belonging to the county authority. The only special school noted is one for 36 mentally defective children at Tonbridge. Dental work shows progress, especially in the coöperation by the parents; in some schools the percentage of acceptances was 100, and fitting tribute is paid to the teachers. The dental trophy awarded to the school at Goodnestone shows the keen interest taken by remote villages. Mr. F. J. Saunders, L.D S., says the increase of parents accepting dental treatment has so occupied the staff that inspections are only half what they were three years ago; the other children only receive dental treatment when it is applied for, usually as a result of toothache. Mr. L. F. Hayes, L.D.S., remarks that the centres are unable to deal with the whole school population, even when working to capacity. He stresses the value of the dental habit; now that almost the whole life of the individual is covered by dental schemes under (1) child welfare centres, (2) school dental centres, (3) dental benefits under the Insurance Acts, there can be little excuse for dental unfitness. The criterion of success in school work is the percentage of children leaving school dentally fit. Dr. Greenwood adds that rather fewer children are having dental treatment for the first time, and more are re-treated, and that this is inevitable unless the dental staff is expanded. The oculist, Dr. J. W. Fox, speaks of the value of covering the "good eye" when the other is squinting or amblyopic. He cites several examples of benefit, in some of which the vision in the weak eye was raised from 6/60 or less up to 6/9 or more. The disadvantages are trivial, and failure is due to not persisting for the necessary minimum of six months; the process should then, he says, be continued during alternate months for another year. Included in the report are the results of some special inquiries by members of the staff. Dr. Dorothy Gallie deals with faults in clothing and footwear. Dr. H. J. Phillips traces some connexion between rheumatism and nose and throat conditions; incidentally he notes that the results of operation were unsatisfactory in 24·4 per cent. of cases. Dr. J. Selfe attributes much debility to incorrect feeding. Dr. F. Wolverson finds evidence that the midday meal brought from home is inadequate; if a school canteen cannot be provided, something should be done to augment the fare by the provision of cocoa or (far better) milk. Dr. W. Lessey describes some types of neuropathic child. Dr. S. A. Tucker's notes on enuresis are of general interest.

Leicestershire.

Dr. J. A. Fairer directs attention to three links in the coördination of infant welfare and school work: (1) Community of staff. (2) Arrangements for transfer of records, especially of the physically defective. (3) Extension of ophthalmic treatment to all necessitous pre-school children. Elsewhere he notes a fourth—namely, infant welfare exhibitions, of which two have been arranged by the superintendent school nurse, and attended by many of the elder school girls to whom she also gives oral instruction. There are in the county no nursery schools, it is true, but the need for them is not such as it is in crowded towns. Dr. Fairer is impressed with the importance of after-care, especially in the case of crippled children whose surgical appliances need constant revision; much is hoped from the formation of local committees associated with the rural community councils. By such means cripples and other defective children of pre-school age would be looked after better. Of the orthopædic work in the county he speaks with appreciation; it includes ascertainment, orthopædic hospitals, clinics and agencies like the Loughborough Cripples' Guild. Massage, electrical treatment, exercises and re-education, ultra-violet radiation and surgical appliances are all provided, the only missing feature is the special P.D. school, the establishment of which in rural areas undoubtedly presents difficulties. Mr. Percy Ashton, L.D.S., has made an investigation of the condition of the teeth in children leaving school; 85·6 per cent. of the children examined had sound permanent teeth, 39 per cent. being naturally sound, and the remainder rendered sound by dental care. The treatment of defective vision is carried out by Dr. Constance Walters, who has made a special inquiry into myopia. It was found that up to five dioptres the incidence of each grade rose steadily with age; above five dioptres this did not hold, probably because the higher degrees of myopia are due to congenital defect. Myopia was not discovered in pre-school children, but diagnosis at this age is difficult. Dr. Walters has also investigated the relation of visual troubles to defective lighting in schools; the percentage of children wearing glasses or showing symptoms of eyestrain was markedly greater in the worse lighted schools, 19·4 against 12·3. Dr. Mary Weston has studied the causes of fatigue in secondary school girls. The hours per week devoted to specific school activities were noted and features of the home life also considered. It was found that there were very wide variations in both groups; hours given to class work and preparation amounted to 31 at some schools for girls of 14, and only 20½ at others. Some girls got 11½ hours sleep at night, some only 7½. Dr. Weston regards concerted action by parents, head teachers, physical training instructors, and doctors as seriously needed.

MENTAL HOSPITAL REPORTS.

The West Sussex County Mental Hospital at Chichester had 877 patients on the books on Dec. 31st last, exactly the same number as the previous year. The recovery-rate was 31·8 per cent. and the death-rate 7·52 per cent. The hospital suffered from influenza, enteric, scarlet fever, and tonsillitis; the medical superintendent remarks that overcrowding must have contributed to these epidemics to some extent. The dietary has been improved. Leave has been granted freely, and on an average 50 patients have had parole within the grounds and 29 more outside. The medical superintendent thinks that there has been a decrease in the public fear of mental hospitals and quotes three interesting cases to show the demand for treatment. The consulting surgeon performed three operations and the consulting rhinologist one. An advanced case of general paralysis was treated with malaria at the Hants County Mental Hospital and showed some physical improvement. The hospital already has an X ray plant, and ultra-violet light is to be provided when the new admission hospital and treatment centre is completed. The visiting commissioner suggests the appointment of an occupations officer. Six nurses and three attendants obtained their R.M.P.A. certificate during the year.

The Staffordshire Mental Hospitals' Board have three hospitals under their care. At Stafford there were 1042 patients resident at the end of last year and the overcrowding has become accentuated. Plans for an admission hospital have been approved, but building has not yet been commenced. The recovery-rate for the year was 33·6 per cent. and the death-rate 8·07 per cent. General paralytics have

been treated by sulfarsenol and biscam; tryparsamide has been abandoned in favour of these preparations as they are much less toxic and give better results. In the laboratory a good deal of work has been done on bacterial toxins, and the presence of hæmoglobin reductases in exotoxins of certain coliform organisms has been established. The metabolism of epilepsy and primary dementia has been investigated biochemically. One ward on each side and the isolation hospital, which is occupied by men, are administered on the "open door" principle. Three men have full parole and two women and 33 men are free within the estate. The general health has been good, except for three cases of erysipelas and 17 of tuberculosis. Women nurses are not employed on the male side. Five attendants passed the final examination of the R.M.P.A. during the year.

At BURNTWOOD there were 940 patients in residence on Dec. 31st last, and consequently considerable overcrowding. It is hoped to build an admission hospital very soon. The recovery-rate was 35 per cent. and the death-rate 9·88 per cent. No less than 78 per cent. of the discharged patients had preliminary periods of trial, many of them with money grants. There was a small outbreak of Flexner dysentery, and the tuberculosis rate is high, as the patients come from a densely populated area. Several operations have been performed, and X ray examinations are carried out by arrangement with a local hospital. Raffia and rug-making have kept a number of patients occupied. A trained laboratory assistant has been appointed, and a number of pathological examinations have been made. About 10 per cent. of the male patients have parole and two wards each side are conducted on the open-door system. The visiting commissioner urges the provision of a clinical room for each ward. Two dental surgeons visit fortnightly. Four attendants gained the R.M.P.A. certificate during the year.

At CHEDDLETON there were 1128 patients at the end of last year. The medical superintendent notes a definite increase in the number of depressed middle-aged male cases admitted—the men whose services are first dispensed with when trade falls off and orders are few. In 95 per cent. of the fatal cases post-mortem examinations were made. The Wassermann reaction has been tested in all new admissions—i.e., 233. Of these, 24 men and 5 women gave a positive result; 20 men and 3 women had general paralysis. Malarial treatment is given to all who show a positive serum. It seems to be the first rigor which is the only effective one, and any spirochætes that survive the first rigor can stand any number of subsequent ones. Of the cases treated by malaria during the last seven years, roughly one-third recovered, one-third were arrested, and one-third were not improved or died. A searching investigation has been made into the possible reasons for the high percentage of tuberculosis in the hospital. The medical superintendent declares that tuberculosis can be abolished from mental hospitals if the public choose; it is all a question of money, for the cases must be properly segregated. There were 31 cases of dysentery in the hospital during the year, with two deaths. The medical superintendent is anxious to have an X ray installation. Parole outside the estate is given to 60 men and 21 women and within the grounds to 30 men and 5 women; three wards on each side are "open door." There are a number of children in the hospital, who are taught with great care; an occupational organiser visits from time to time.

The HERTFORDSHIRE COUNTY MENTAL HOSPITAL at ST. ALBANS had 881 patients at the end of last year. The recovery-rate was 28·6 per cent. and the death-rate 7·19 per cent. Post-mortem examinations were made in 48 out of the 71 fatal cases. A male annexe has been opened for bedridden men and has slightly relieved the overcrowding. A nurses' home was opened in January, and there are plans for providing another 350 beds. The general health was satisfactory except for a few cases of dysentery. Eight patients only are suffering from tuberculosis. General paralysis has been treated with tryparsamide, and two cases have been given malarial inoculation. Dental treatment was given to 58 men and 81 women and an organised effort was begun during the year to tackle the problem of eliminating septic foci. An ear, nose and throat surgeon has been appointed, and visits monthly. Ten operations were performed during the year. There is a physical drill class for men and a handicraft class for women, and the canteen is running successfully. Many routine investigations were carried out in the laboratory, which also does some work for the county mental officer of health. Eight men and eight women have parole beyond the estate, and 26 men within the grounds. The visiting commissioner suggests the desirability of installing X rays, ultra-violet rays, continuous baths, and cinema. No female nurses work on the male side. Six nurses and two attendants obtained their certificates during the year.

The report of the DOWN COUNTY MENTAL HOSPITAL is illustrated with a number of photographs, including an aerial view. There were 774 patients on the books at the end of last year. The recovery-rate was 34·3 per cent. and the death-rate 9·5 per cent. The latter shows a considerable increase on account of influenza. Schemes for supplying electromedical and hydrotherapeutic installation, verandas, and shelters have been approved. Rooms have been adapted for occupational therapy with great success. There was a great deal of paratyphoid, coincident with a widespread epidemic in the neighbourhood, and there was an outbreak of swine fever in the farm at the same time. Four attendants and six nurses obtained the R.M.P.A. certificate during the year.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 6TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 106 (last week 99); scarlet fever, 1411; diphtheria, 1074; enteric fever, 82; pneumonia, 440; puerperal fever, 36; puerperal pyrexia, 92; cerebro-spinal fever, 7; acute poliomyelitis, 24; acute polio-encephalitis, 2; encephalitis lethargica, 10; dysentery, 10; ophthalmia neonatorum, 108. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Sept. 9th–10th was as follows: Small-pox, 216 under treatment, 4 under observation (last week 209 and 5 respectively); scarlet fever, 1449; diphtheria, 1671; enteric fever, 31; measles, 135; whooping-cough, 104; puerperal fever, 27 (plus 14 babies); encephalitis lethargica, 119; "other diseases," 35. At St. Margaret's Hospital there were 16 babies (plus 8 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 2 (0) from enteric fever, 10 (1) from measles, 8 (2) from scarlet fever, 9 (1) from whooping-cough, 14 (7) from diphtheria, 50 (11) from diarrhœa and enteritis under two years, and 10 (6) from influenza. The figures in parentheses are those for London itself.

The deaths from enteric fever outside London occurred at Northampton and Cardiff. Liverpool reported three deaths from measles and 2 from diphtheria. Four deaths from diarrhœa were reported from Liverpool, 3 each from Birkenhead and Newcastle-on-Tyne, 2 each from Leicester, Manchester, Middlesbrough, and Swansea.

The number of stillbirths notified during the week was 264 (corresponding to a rate of 38 per 1000 births), including 44 in London.

ENLARGEMENT OF BURTON INFIRMARY.—Extensions to Burton-on-Trent General Infirmary are being made at a cost exceeding £17,000. The work includes an enlargement of the out-patients' department, and the erection of a new X ray department with the necessary accessories, a casualty ward with a new dispensary, a throat and ear department, and improved accommodation for nurses.

CORRESPONDENCE

POSTURE IN HEALTH AND DISEASE.

To the Editor of THE LANCET.

SIR,—May I return to your report [1] of an address on this subject recently given by Miss M. Forrester-Brown to the London Association of the Medical Women's Federation. This report interested me greatly, but in view of the conclusions arrived at by no less a scientist than the late Rudolph Magnus, I am surprised to note that it attributed to Miss Forrester-Brown the following statement: "The position of the head is relatively unimportant in connexion with good posture, for the reflex motor system is at peace provided the eyes are horizontal." Now Magnus, after 14 years' experimentation, arrived at the opposite conclusion, and the details of his work are available to all of us through your columns.[2] It is significant that Sir Charles Sherrington made the "central control" discovery of Magnus the subject of a speech when President of the Royal Society. As the subject of posture in health and disease is of vital importance to every doctor, and as Miss Forrester-Brown has indirectly thrown out a challenge to Magnus and put a shadow of doubt into our minds, may I ask her to give us details of the scientific experimentation which has led her to the very opposite conclusion to that which was reached by Magnus?

I am, Sir, yours faithfully,

Bolton, Sept. 11th, 1930. M. DOUGLAS, M.B.

THE MEDICAL TREATMENT OF CANCER.

To the Editor of THE LANCET.

SIR,—It is really very difficult to express oneself politely, although I do not feel in the least degree acrimonious, when one has to deal with statements such as those of Dr. Todd, for they have their origin in scientific ignorance, verbal inaccuracy, and gross misrepresentation. These are capital offences from an intellectual point of view; and, as with all capital offences, they must be expiated. Moreover, Dr. Todd has advanced no extenuating circumstances to account for his failings: indeed, in his present letter (THE LANCET, Sept. 13th, p. 611) he makes matters worse.

With regard to his reference to the correspondence that has taken place in respect of his claim for priority in the use of lead selenide in the treatment of cancer, you would not have space for the private letters, much as I should like to publish them; I will, therefore, simply quote a short letter that I wrote to you on March 19th, 1927, a week after Dr. Todd's first note (THE LANCET, March 12th, 1927). The letter runs:—

"I have been interested in the brief account by Dr. A. T. Todd of the initial results obtained in some of the cases of malignant disease treated by him with "lead-selenium colloid" (THE LANCET, March 12th, 1927, p. 575). The possibilities of a combination of these elements occurred to me, and doubtless to many others, long ago; and, as a matter of fact, our physical chemists had no difficulty in making an excellent colloid of lead selenide. But what will ultimately prove to be the most useful preparation of lead one can foretell at the present time. Since many preparations of lead will probably be found to affect to a greater or lesser degree malignant neoplasms, what are really needed are comparative studies in regard to a large number of combinations rather than isolated observations of one particular preparation. This is the line our own clinical investigations have taken."

[It was not in respect of this letter that Dr. Todd wrote to me, but in connexion with what occurred in London in 1928, and I shall quote what I then said about Dr. Todd directly.]

In any case it would be puerile for us, who have progressively made and tested some hundreds of preparations of lead colloids to claim any priority beyond that of the use of colloidal lead and colloidal lead compounds in general for the treatment of cancer. However, for the information of Dr. Todd I may say that we commenced the manufacture of lead selenide in October, 1926, and in a private report dated Jan. 10th, 1927, from Prof. Lewis's laboratory for circulation among the staff of the Liverpool Medical Research Organisation, the preface to the description of the preparation of this compound contains the words:—

". . . it was thought by the clinical workers that a compound of this element [selenium] with lead might repay clinical investigation . . . As far as is known a colloidal solution of this compound has not been prepared before, and the details are therefore recorded."

We found, as I have said before, that this preparation is of little value in comparison with other preparations. I give the above quotation to show that in the circumstances I was not ungenerous when I subsequently published at Dr. Todd's request in the *British Medical Journal* (July 7th, 1928, p. 35) the following remark in support of his claim to have worked independently in this connexion:—

". . . the work at Bristol, although based on our work in Liverpool, has been conducted entirely independently . . ."

I should like to inquire in this connexion exactly why in his present letter Dr. Todd says "that the system as described [by Dr. Todd] has been originated here from the work of others and ourselves and owes nothing more to him [W. B. B.]," in view of the fact that he commences his first publication (THE LANCET, March 12th, 1927, p. 575) with the following words:—

"The article published by Prof. Blair Bell on the action of colloidal lead on cancer (THE LANCET, 1925, ii., 793) suggested independent research."

His second communication ("Chemotherapeutic Researches on Cancer," Arrowsmith, 1928) starts in a similar fashion:—

"The promising results of the action of colloidal lead on cancer claimed by Prof. Blair Bell in his article of 1925 determined me to experiment independently, a part of the attraction being a study of the resultant blood changes. We all know the results of his treatment now, but at the time stated proofs were not nearly so complete. The results themselves . . . encouraged the hope that colloidal lead would be of use."

[Of course, our first publication, never mentioned as far as I know by Dr. Todd, appeared in 1922.]

Now, Sir, finding these acknowledgments fatal to his pretentions, Dr. Todd has shifted his ground, or rather turned a complete somersault. He now states that in the treatment of cancer with lead selenide the lead is inert and is merely used by him "as a vehicle for selenium" (!) I confess that such an astounding assertion paralyses my powers of commentation. Is it necessary to add that selenium was extensively tried in the treatment of cancer and found wanting, long before Dr. Todd took it up? Why did Dr. Todd not immediately write dissociating himself from the views expressed in your leading article (THE LANCET, August 23rd, p. 406), where you clearly attribute his results to lead?

[1] THE LANCET, 1930, i., 32.
[2] THE LANCET, 1926, ii., 531 and 585.

The interesting announcement that Dr. Todd intends to give up lead in the treatment of cancer in favour, I suppose, of selenium, already discredited, should be noted by those who imagine that patients are treated in Bristol by the method introduced by us.

I am, Sir, yours faithfully,

Liverpool, Sept. 13th, 1930. W. BLAIR BELL.

RESEARCH DEFENCE SOCIETY.

To the Editor of THE LANCET.

SIR,—I wish I could persuade more members of the medical profession to be subscribers to the Research Defence Society. We do not need any large sum, but if we could get two hundred more annual subscribers of £1, it would make our work easier to carry on. We are the only society that exists to expose the mis-statements of the antivivisection societies and agitators. They preach that all experiments on animals are useless, that no good has come from them to man or beast, and that the experiments are grossly cruel. An uninformed public accept such statements as true, and the only way to get the facts known is by the propaganda of a society such as ours. But this is expensive—and so I ask the help of those who wish it well.

I am, Sir, yours faithfully,

KNUTSFORD,
Chairman, Research Defence Society.

11, Chandos-street, Cavendish-square, London, W., Sept. 16th, 1930.

UNDESIGNATED PASTEURISED MILK.

To the Editor of THE LANCET.

SIR,—Dr. Duncan Forbes's dictum, that the safest liquid milk from the point of view of tuberculosis and sore-throat infections is pasteurised milk, will not be supported elsewhere in the country. Brighton is fortunate in possessing modern pasteurisation equipment. But in other parts of the country there is no doubt that inefficient pasteurisation apparatus still exists. I have recently come across cases of infantile diarrhœa that were reported to be fed on so-called pasteurised milk. Dr. W. G. Savage, in his recent authoritative work, has stressed the dangers of inefficient pasteurisation. This view was upheld by various veterinary surgeons in the discussion at the Royal Society of Medicine (THE LANCET, 1929, ii., 1205), who contended that so-called pasteurisation was making milk dangerous instead of safe for consumption.

I am, Sir, yours faithfully,

Bristol, Sept. 10th, 1930. FRANK BODMAN.

INDUSTRIAL TRAINING FOR THE TUBERCULOUS.—The committee of management of Peamount Sanatorium, Co. Dublin, has established a system of industrial training for tuberculous patients as a step toward the setting-up of a village settlement on lines similar to that at Papworth. The department of Local Government and Public Health of the Irish Free State, has, it is understood, promised its consent to the payment by Boards of Health of certain fees on behalf of patients undergoing training. The Peamount committee states that 31 patients are receiving industrial training with a view to permanent employment by the Peamount Industries. Goods are produced and sold on an economic basis. The ultimate aim is to provide a village settlement for the tuberculous of the Free State, and Dr. P. C. Varrier-Jones, the founder and medical director of Papworth, has undertaken to supervise its development.

MEDICAL NEWS

Post-graduate Courses in Berlin.

Besides the regular programme of post-graduate study a series of special courses are being held in Berlin during the autumn. The subjects include laboratory work (Sept. 29th to Oct. 4th), internal medicine (Oct. 6th to 18th), children's diseases (Sept. 29th to Oct. 11th), the eye (Oct. 1st to 11th), the ear, nose and throat (Oct. 13th to 25th), intrathoracic disease, especially tuberculosis (Oct. 20th to 24th), occupation and illness, with special consideration of assessment of Efficiency (Oct. 27th to Nov. 4th). The courses are held in German, but many of the lecturers speak English. Particulars may be had from the information bureau of the Kaiserin Friedrich-Haus (Berlin, N.W.6, Luisenplatz 2), which offers help in procuring suitable lodgings and arranging attendance at clinics. Further courses will be held in the spring.

A Course in Cardiology.

Dr. C. Laubry will take charge of a course on Diseases of the Heart and Vessels to be held at the Hôpital Broussais, rue Didot, Paris, from Oct. 13th to 25th. Particulars are obtainable from Dr. Mevel at the hospital.

Congress of Orthopædics.

The Société Française d'Orthopédie will hold its twelfth reunion at 9.30 A.M. on Friday, Oct. 10th, at the Faculty of Medicine (Amphithéâtre Vulpian), Paris. The subjects of discussion will be Coxa Vara in Adolescents and Obstetrical Paralyses of the Upper Limb. The Secretary-general is Dr. E. Sorrel, 179, Boulevard Saint-Germain, Paris.

Hygiene in the Tropics.

Lectures and demonstrations for men and women, outside the medical profession, proceeding to the tropics, will be given at the London School of Hygiene and Tropical Medicine by Lieut.-Colonel G. E. F. Stammers, on Oct. 8th, 9th, 10th, 13th, 14th, 15th, 16th, and 17th, from 11 A.M. to 12.30 P.M.

Medical Women's Federation.

The annual conference of the psychological section of this Federation is to be held on Saturday, Oct. 18th, at The Lawn, Lincoln. Dr. Alice Hutchison will speak on Child Guidance in Relation to Juvenile Delinquency, and there will be an informal discussion on The Local Government Act and Mental Treatment Act, and how they affect the Treatment of Mental Disorder.

Instruction for D.P.H.

A three-months' course of lectures and demonstrations on clinical practice and in hospital administration will be given at the North-Eastern Hospital, St. Ann's-road, Tottenham, London, N., by Dr. F. H. Thomson, Medical Superintendent, on Mondays and Wednesdays at 4.45 P.M. and alternate Saturdays at 11 A.M., from Oct. 1st. Application should be made to the Medical Officer of Health, London County Council, Public Health Department (Special Hospitals), Victoria Embankment, E.C. 4.

Fellowship of Medicine and Post-Graduate Medical Association.

From Sept. 29th to Oct. 11th, at the Metropolitan Hospital, Kingsland-road, E., there will be an all-day course in medicine, surgery, and the special departments. The subjects of special courses in October are as follows: diseases of ear, nose, and throat (Oct. 6th to Nov. 1st); tropical medicine (Oct. 6th to 25th, all day); gynæcology (Oct. 13th to 24th); diseases of children (Oct. 27th to Nov. 5th); and orthopædics (Oct. 27th to Nov. 5th). There will also be evening courses in preparation for the M.R.C.P. examination (17 lectures on Tuesdays and Fridays), and for the Final F.R.C.S. examination (six demonstrations on Wednesdays). Particulars and syllabuses of all courses may be obtained from the Secretary of the Fellowship at 1, Wimpole-street, London, W.

Ben Ulster Hospital.

The annual report of this eye, ear, and throat hospital at Belfast states that last year 785 in-patients were admitted; new out-patients numbered 6390. The constant growth in the number of patients has necessitated additions and alterations, and the old female ward has been converted into private wards. During the year there were 1022 operations, 29 of them for cataract.

Staffordshire General Infirmary.

The 1549 in-patients last year stayed on an average 15½ days, half a day less than in 1928, and their cost, less an estimated amount for out-patients, was £6 5*s.* 6*d.* Of the 2113 out-patients half were ophthalmic (628) or nose, throat and ears (463) cases. The ordinary income, £8798, was the largest on record.

OBITUARY

MICHAEL BEVERLEY, M.D. Edin.

Dr. Michael Beverley, who died at Overstrand on August 31st, was a magistrate of Norwich for 55 years, and one of the principal medical men in Norfolk. His father was also Michael Beverley and came of an old Norfolk family. The son was born in 1841, and on leaving school was apprenticed to Mr. W. B. Francis, a local surgeon. At the age of 16 he was already visiting the sick and vaccinating babies. At the Norfolk and Norwich Hospital he learnt the art of notetaking under Mr. Firth and Dr. Eade, and with this experience behind him entered King's College Hospital, where he dressed for Sir William Ferguson. Proceeding to Edinburgh he worked under Syme and Simpson, and graduated before the legal age of 21. This allowed him to spend a year in Paris, where he followed the clinics of Trousseau, Vélaton, Roger, and Giraldè's, and lived in the narrow 4d rue de Seine. These were the palmy days of the 1st Empire, and Beverley found them enlivening and picturesque. But at the end of the year the post of house surgeon at the Norfolk and Norwich Hospital fell vacant, and he secured the appointment. Thus, in 1864, he began an association which remained almost unbroken till his retirement in 1913. After more than six years as resident medical officer, and (as he said) "practically lady superintendent" as well, he went to the Rotunda to rub up his knowledge of midwifery, and from Dublin back to Edinburgh with an introduction to Lister. He returned an enthusiastic convert and proceeded to carry out Listerian principles at Norwich. In practice he entered partnership with William Cadge, a notable figure in British surgery, and the association was a happy one. During the long years of practice which followed he won a reputation not only as an able surgeon, but as a generous and valuable friend of his hospital, his colleagues, and his patients. He was, moreover, an enthusiast for his county. He was more or less the "discoverer" of Overstrand as a holiday resort, and he had a house there for his family 40 or 50 years ago. In 1920 he moved from Scole to Overstrand and lived there permanently thenceforward. The Brundall Gardens, which were laid out under his supervision, testify to his success in landscape gardening which was a lifelong hobby.

Dr. Beverley married Marion, daughter of John Colbatch, J.P., but was left a widower in 1917. One of his sons, Michael, was killed in the war. One son survives, and four daughters.

HUGH SMITH, M.D. Lond., F.R.C.S. Eng.

THE death of Dr. Hugh Smith on July 2nd is deeply regretted in South Africa and comes as a serious loss to the teaching staff of the medical faculty of Cape Town. Born in London in 1863, the son of Hugh Smith, of Darvel, in Ayrshire, he was educated at the City of London School and the London Hospital. He graduated in 1886 and became M.D. and F.R.C.S. two years later, having meanwhile served as house physician to Hughlings Jackson and as resident accoucheur at the London. From 1891 onwards he practised in Leghgate, but in 1900 went to join the late Sir Alfred Jamson in partnership at Cape Town, where he rapidly established a reputation for accurate diagnosis. His opinion was frequently sought by fellow practitioners, and these demands became so exacting that eventually he gave up general practice and undertook consultant work alone. He is said to have been the first consultant in South Africa, and at first his position was understood with difficulty by his patients. But his position was soon assured by the quality of his work. To charm of manner he united a quiet and forceful personality. General Botha, a notoriously difficult patient, said of him: "That Dr. Smith is different from you doctors. He's not the sort of man you can quarrel with." He was an active member of the British Medical Association for many years, and in 1914 he was elected president of the Western Province branch; when the Medical Association of South Africa was established he gave it whole-hearted support, although he had been in favour of retaining the parent association. He was honorary visiting physician to the New Somerset Hospital from 1902 to 1919, and on his retirement from that post became a member of the consulting staff; during the late war he held the position of consultant to the military hospitals at Wynberg and Maitland. Until the time of his death he was a member of the Faculty of Medicine of Cape Town University and lecturer on dermatology. In 1921 he was elected to the presidency of the Seventeenth South African Medical Congress which met that year in Cape Town. His energy, kindliness, and wide human sympathies were responsible for the affection and esteem felt by patients and colleagues alike.

THOMAS WALLACE, M.D.R.U.I.

Dr. Thomas Wallace was an important figure in the city of Cardiff for half a century, and his death on Sept. 5th ends a long life of useful work for the city. He was born in County Antrim in 1849, the son of Thomas Wallace, and was educated at Coleraine and at Queen's College, Belfast. Graduating there in 1870, he became M.R.C.S. Eng. two years later. From '77 to '82 he was medical officer to out-patients in the Cardiff Infirmary, then he joined the staff as surgeon, and in 1905 became consulting surgeon. Meanwhile he had built up a large practice and was widely known as medical officer of friendly societies, surgeon to the Bute Docks Police, and a referee under the Workmen's Compensation Act. At the same time he threw his energy and influence into many kinds of social, educational, and benevolent work, especially for the Royal Infirmary. A Justice of the Peace for Cardiff since 1892, he was appointed a Justice for the County of Glamorgan in 1903. During the late war he served on the staff of the 3rd Western General Hospital, with the rank of Lieut.-Colonel, and for many years he was closely associated with the activities of the Order of St. John of Jerusalem. In 1928 he was elected Grand Superintendent of the Provincial Grand Chapter of Royal Arch Masonry in South Wales.

"It can truly be said of Dr. Wallace," writes a colleague, "that he was a striking personality, one in whom confidence was inspired and retained with complete justification, for he rang true every time. He was kindly disposed and of a lovable nature, always ready and willing to find out and listen to the other man's point of view. He was a man of strong convictions and never hesitated to declare them when it was necessary to do so, but their declaration was always tempered with kindliness, and this probably explains why he had such a wide circle of friends and so few, if any, enemies. Those of us

who knew him and worked with him pay tribute to his sterling worth. The nation and the profession can do with more men of his strong rugged personality."

Dr. Wallace married Margaret, the daughter of the late Dr. C. R. Vachell. She died in 1916. He was long assisted in practice by his nephew, Dr. Tom Wallace, and he leaves a family of five married daughters and two sons, one of whom is Dr. John Wallace, of the Ministry of Pensions.

ROWAN McCOMBE, F.R.C.S.Irel., D.P.H.

Dr. McCombe, who died at Margate on Sept. 11th, in his 60th year, was the first whole-time medical officer of health for that borough. He was a student of the Meath Hospital, Dublin, qualifying in 1892 and taking the Irish surgical fellowship and the diploma of public health some ten years later. He settled in Margate about 25 years ago, and became surgeon to the Cottage Hospital and hon. medical officer to the Cripples' Holiday Home. On the death, in 1914, of the part-time medical officer of health, Dr. Bertram Thornton, the local authority decided to make the position a full-time one, and appointed Dr. McCombe medical officer of health and school medical officer. Among his duties he was medical adviser to the child welfare centre and he was also police surgeon to the borough. Dr. McCombe leaves a widow and two children.

THE LATE DR. LEONARD MARK.

Sir D'Arcy Power writes: "Few persons have described a disease from which they have themselves suffered. The outstanding instances are Montaigne and Pepys as laymen; Thomas Sydenham and Leonard Mark as doctors. Montaigne and Pepys only give details incidentally and as they affected their general life. Sydenham and Mark made more careful studies and yet each in a wholly different manner. Sydenham in his 'Tractatus de Podagra' used his own experience as a basis for a description which soon became classical and, as gout has now become rare, is unsurpassable. But he went into no minute details and dealt rather in generalities, using his personal knowledge to illustrate the thesis. Leonard Mark, on the other hand, in his book on 'Acromegaly' published in 1912 and in the 'Apologia' which appeared 15 years later, aimed at giving a minute and complete account of the disease as it occurred in a single case—viz., in himself. He traces it from the insidious beginning, and by means of photographs shows the physical changes which it caused in his own person. Pursuing his object he records the changes which took place in his eyes, in his skull, and in his brain, obtaining written opinions from those amongst his many friends who were masters in their own branches of knowledge. Finally, to complete the record he left directions that his skull and brain should be examined after death by a competent pathologist. Not content with a study of the physical side he placed on record the mental states involved which he alone could treat adequately. The headaches; the lethargy; the subjective noises and the varying feelings of depression. Yet all is done in a scientific spirit and without undue introspection or any self-pity and in this lies the value of the record. A notable example of the mens sana in corpore insano, and so an exception to the general rule. Whether it were worth while to have done it is another matter. Occasionally 'yes' when the patient can take so detached a view of his malady, but an example not to be copied too frequently, especially in this age of sentiment."

Medical Diary

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUAT MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Sept. 22nd, to SATURDAY, Sept. 27th.—WES MINSTER HOSPITAL, S.W. Post-graduate course i medicine and surgery and the special department occupying each day from 10.30 A.M. to 5.30 P.M., wit lectures and demonstrations. Men only.—Furth particulars from the Fellowship of Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Sept. 22nd.—2.30 to 5 P.M.: Medical, Surgical, an Gynæcological Clinics. Operations.
TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nos and Throat Clinics. Operations.
WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Ey Clinics. Operations.
THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M. Medical, Surgical, Throat, and Ear Clinics. Operation
FRIDAY.—10.30 A.M.: Ear, Nose, and Throat Clinics. 2.3 to 5 P.M.: Medical, Surgical, and Children's Disease Clinics. Operations.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE Hammersmith, W.
MONDAY, Sept. 22nd.—10 A.M. to 1 P.M., Surgical Ward Genito-Urinary Operations, Skin Department. 2 P.M Operations, Surgical Wards, Medical, Surgical, Ey and Gynæcological Out-patients.
TUESDAY.—10 A.M. to 1 P.M., Medical Wards, Clinic Demonstration (Surgical Dental Department). 2 P.M Operations, Medical, Surgical, and Throat Out-patient
WEDNESDAY.—10 A.M. to 1 P.M., Medical and Surgic Wards, Children's Medical Out-patients. 2 P.M Gynæcological and General Operations, Medica Surgical and Eye Out-patients.
THURSDAY.—10 A.M. to 1 P.M., Neurological Out-patient Demonstration of Fractures. 2 P.M., Operation Medical, Surgical, and Genito-Urinary Out-patient
FRIDAY.—10 A.M. to 1 P.M., Medical Wards, Skin Depar ment, Dental Department, Clinical Demonstratio (Medical). 2 P.M., Operations, Medical, Surgical an Throat Out-patients.
SATURDAY.—10 A.M. to 1 P.M., Throat Operations, Bacteri Therapy Department, Medical Wards, Children Medical and Surgical Out-patients.

CENTRAL LONDON THROAT, NOSE, AND EAR HOS PITAL, Gray's Inn-road, W.C.
FRIDAY, Sept. 26th.—4 P.M.: Mr. J. D. McLaggan Tuberculosis of the Larynx.

Appointments

LEWIS, IVOR, M.B. Lond., D.P.H., Medical Officer of Health f Plymouth and Superintendent of the City Hospital.
TOLEMAN, R. J., M.B. Lond., Assistant Medical Officer Health and School Medical Officer for Bristol.
Certifying Surgeons under the Factory and Workshop Acts COLLINS, E. A., L.R.C.P. Lond., M.R.C.S. (Saxmundham) CHISHOLM, J. P., M.B., Ch.B. Glasg. (Somercotes, Lincoln) and JOHNS, L. P., L.R.C.P. Lond., M.R.C.S., St. Blaze (Cornwall).

Births, Marriages, and Deaths

BIRTHS.

GORDON.—On Sept. 11th, at Welbeck-street, the wife Dr. Hugh Gordon, of a son.
WRIGHT.—On August 25th, 1930, to Miriam, wife of Samso Wright, M.D.—a daughter.

MARRIAGES.

CURNOCK—OWEN.—On Sept. 6th, at Epping, J. Edgley Curnoc M.R.C.S., L.R.C.P., L.D.S., to Muriel Owen.
FITZGERALD—SLATER.—On Sept. 10th, at Dunedin, N.Z H. Walden Fitzgerald, F.R.C.S., to Alfreda Hurwort only daughter of Mr. and Mrs. Alfred Slater, Wallesey.

DEATHS.

ARTHUR.—On Sept. 9th, at Blackhall Wood, Carlisle, Lieut.-Co A. S. Arthur, O.B.E., R.A.M.C., Retired Pay.
ASLETT.—On Sept. 6th, at Tiverton, George Stratton Aslet M.B., aged 70.
CLARKE, WILLIAM FREDERICK, M.D. Lond., who practised Fulham, London, and later in Toronto, Canada, died Berkeley, California, on Sept. 12th, 1930.
KELLGREN.—On Sept. 11th, at Eccleston-square, Victoria, S.W Dr. Ernest Gregor Kellgren.
MCCOMBE.—On Sept. 11th, at Heronden, Margate, Rowa McCombe, F.R.C.S.I., D.P.H.Camb., Medical Officer Health for Margate, aged 59 years.
SAWYER.—On Sept. 10th, suddenly, at Horton-lane, Bradfor Henry Sawyer, M.R.C.S.
SKEEN.—On Sept. 6th, at Kilmore Quay, Wexford, suddenly Dr. George Skeen, of Colne, Lancashire, aged 60.
WRIGHT.—On Sept. 12th, at his residence, Carleton-road, N Dr. Holland Hodgson Wright, aged 77.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

THE HEALTH OF BATOUM.

BATOUM, which was ceded by Turkey to Russia in 878 by the Berlin treaty-makers, is a town of some 2,000 inhabitants in a populous neighbourhood. he traveller, who reaches the town from the west y cruising along the north coast of Asia Minor, once e has passed Cape Sinope, enters a new and a milder limate. The sky is blue, the weather is warm, the egetation semi-tropical; and though the view is amed by the snow-clad peaks of the Caucasus, only 0 miles away, the actual temperature throughout he year varies only between 104° and 40°F. A rain- all of 100 inches gives plenty of water: the fertile oil produces tea, tobacco, cotton and maize, besides any fruits. The other chief exports are manganese res, light oil conducted from Baku along a 600-mile ipe line, and heavy oil. But there is a seamy side o the picture as we learn [1] from Dr. Berge, a surgeon- eutenant-commander in the French Navy, who has ade eight visits to the port. Batoum is a semi- astern town of deplorable sanitary conditions, with ttle to spend on sanitation. The diseases causing nxiety are typhoid and typhus fevers, undulant fever, alaria, tubercle, dysentery, trachoma, small-pox, nd venereal diseases, but an efficient quarantine ervice protects it from plague and cholera. There a medical department to deal with threatening iseases, and some 100 physicians, a few with European aining, but most of them educated at Moscow or iflis. Those in charge of the industrially assured e paid £15 a month with liberty to engage in private actice. There are four public dispensaries in atoum, for venereal diseases, tubercle, malaria, and ild welfare, while travelling groups of doctors visit ie neighbouring villages to advise on the prevention cure of illnesses. The civil hospital of 300 beds is ell equipped; the military hospital even better. revention of syphilis is attempted by a free prophy- ctic station, in charge of a doctor, and always open, it there is not enough propaganda to popularise it. Tolerated houses" have all been closed, as they are garded as a denial of individual liberty. Drugs me mostly from Germany, some from Moscow, but ere are four laboratories in Georgia, which make rums and vaccines. Dr. Berge's last voyage nfirmed his impression of rising cost of living, creasing poverty, and threatening famine.

OOKED FOOD FOR ARMIES IN THE FIELD.

STARVING soldiers have been inspired to victory 7 great generals; we think of Clive at Arcot, of onewall Jackson in the Shenandoah Valley. But ore even results may be expected if the troops t hot meals regularly, and a recent article,[2] by ajor C. T. Beckett, tells how this is to be managed the British Army. With mechanisation, petrol s become the general service fuel of future wars d will be used for cooking. It will be burned in an l-stove, with a hydra burner (a "combustor," e are told, of the Primus family). The stoves will be four types: a single burner, which will cook for men and will be carried in every armoured fighting hicle; a two-burner stove (pack transport) which ill cook for 50 men (at brigade headquarters and the e); and two varieties of the general service pattern hich will cook for 250—either stationary, for lines of mmunication, or mobile, on a trailer, for the fighting oops. The three larger patterns have an oven which ill roast for half their men.

It was asked whether the cooking need be completed in e trailers. Haybox cooking was considered, but it was ought that hay might be scarce in a modern war, and e problem was studied afresh. For every soldier it is intended that two hot meals of two pints each shall be cooked and distributed daily. A quarter of them will be cooked in pairs of one-gallon stainless steel containers, for men on detachment, and three-quarters in six-gallon containers for the main groups. The food will be brought to the boil in the containers on the oil-stove and at once removed and slipped into boxes of three-ply wood, faced with metal and insulated with kapok, in which cooking will go on until the temperature falls to 140°—i.e., in 10 hours for the smaller, in 17 hours for the larger containers. Thus the usefulness of the kitchen is at least doubled, and it is expected that the soldier will always get his two meals a day well cooked and reasonably hot.

PIONEERS OF PUBLIC HEALTH.

A GOOD many people must have looked at the names inscribed on the new School of Hygiene and Tropical Medicine in Gower-street, and wondered who some of them were; hardly anyone is informed enough to know about them all. Lister, Pasteur, and Jenner are, perhaps, familiar enough, but who are Frank and Lind and Shattuck, and, nearer home, Pringle and Farr? And in these days of spectacular parasitology it is particularly well to be reminded of the great apostles of drains and soap and statistics. We judge, therefore, that Mr. Walker has done a useful service in putting together very readable short biographies [1] (with portraits) of the heroes celebrated on the building; the book will serve its purpose admirably.

A RADIO-ACTIVE COMPRESS.

"Radiumchema" is the trade-mark of radio-active compresses manufactured in the State-controlled chemical works of Kolin with radium derived from the mines at St. Joachimstal, Czecho-Slovakia. The compress which we have received (from Hedges House, 153, Regent-street, London, W.1) measures 6 by 8 in. and is certified by the Curie Laboratories to contain 0·1 mg. of radium. It is constructed so as to conform to the part of the body to which it is applied; it can be taken out of its flannel cover and washed with warm water or disinfectant; and it is kept in place on the affected area by means of a simple bandage. The materials of which it is composed have been assembled under the control of the Radiological Institute of Prague and the Technical Academy in Vienna. The compress is recommended for the relief of pain in many regions of the body as well as for a variety of other conditions. Testimonials from institutes in Central Europe confirm its value in relieving pain; Dr. Markl of the Prague Institute regards the results observed as due to activation of the tissues, to promotion of metabolism by increased lymph flow, and to direct sedative effect on the nerves.

THE USE OF THE MICROSCOPE.

A STRAIGHTFORWARD practical account of microscopic technique with a minimum of theory has been compiled by Mr. J. Belling [2] to help those who use the microscope to get the best out of their instrument. The section on photography is brief, and in the chapter on drawing nothing is said about drawing an image projected on to paper—for many purposes a much more convenient plan than the Abbé camera. There is a full bibliography, and it is pleasant to notice the importance which is attached to the work of the English pioneers.

STANDARDISED COD-LIVER OIL AND MALT.

THE Ministry of Agriculture and Fisheries inform us that every jar of "malt and oil" sold under their National Mark Scheme is legally guaranteed to conform with the following standards:—

Purity: Absolute freedom from adulteration.

Protein Content: Not less than 5 per cent. by weight of soluble protein.

Carbohydrate Content: Specific gravity of the malt extract of not less than 1·4 ensures a high proportion of carbohydrates, which are present in a readily assimilable form.

Cod-liver Oil Content: 15 per cent. by volume of the total mixture, with the permissible variation of 1 per cent. above or below this figure as a margin of error.

To attain National Mark standard malt extract must have a diastatic activity of not less than 25 Lintner. This prescription in the National Mark Scheme of a minimum standard of diastatic activity is said to be an innovation in the trade. Apart from other advantages which may be claimed for diastatic activity, its presence is held to afford a reliable indication that due care has been exercised to ensure that the accessory food factors of malt extract have not been destroyed or seriously reduced by the manufacturing process.

The present retail prices of National Mark "malt and oil" are 1*s.* 3*d.* per 1 lb. jar, and 2*s.* 4*d.* per 2 lb. jar.

Vacancies

For further information refer to the advertisement columns.

Alderley Edge, Ancoats Hospital, Convalescent Home, Great Warford.—Hon. Visiting Physician. £50.
Archway Hospital, Archway-road, Highgate, N.—Asst. M.O. £300.
Aylesbury, Royal Buckinghamshire County Hospital.—Hon. Consulting Surgeon to Throat, Nose, and Ear Dept.
Barnstaple, North Devon Infirmary.—Res. M.O. At rate of £150.
Bath, Royal United Hospital.—H.S. At rate of £150.
Birmingham, Ear and Throat Hospital, Edmund-street.—Res. Anæsthetist. At rate of £150.
Birmingham, Selly Oak Hospital.—Cas. O. £200.
Bradford City.—Vacancies on Staff of City Pathologist and Bacteriologist. £600.
Brighton, Royal Sussex County Hospital.—Cas. H.S. £120.
Bristol General Hospital.—Hon. Dental Surgeon.
Bury Infirmary, Lancashire.—Third H.S. At rate of £150.
Cardiff, Glan Ely Tuberculosis Hospital, Fairwater.—Asst. Res. M.O. £250.
Central London Throat, Nose, and Ear Hospital, Gray's Inn-road.—Two Hon. Assts. for Out-patient Department.
Chesterfield and North Derbyshire Royal Hospital.—H.S. At rate of £100–£175.
City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—H.P. At rate of £100.
Colchester, Essex County Hospital.—H.P. £150.
Colchester, Royal Eastern Counties Institution for the Mentally Defective.—Research Worker. £750.
Dewsbury, New Dewsbury and District General Infirmary.—2nd H.S. £150.
East Ham Memorial Hospital, Shrewsbury-road, E.—Res. M.O. At rate of £200. Also H.P. At rate of £150. Also H.S. to Special Departments and Cas. O. At rate of £120.
Essex, Administrative County of.—Asst. County M.O.H. £500–£700.
Evelina Hospital for Children, Southwark, S.E.—H.S. At rate of £120.
Exeter, Royal Devon and Exeter Hospital.—H.S. to Special Depts. At rate of £150.
Gloucester County and City Mental Hospitals.—Jun. Asst. M.O. £350.
Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—Second H.S. At rate of £120.
Golden Square Throat, Nose, and Ear Hospital, W.—Hon. Reg. Also Hon. Clin. Asst.
Great Yarmouth General Hospital.—Sen. and Jun. H.S.'s. £150 and £140 respectively.
Hackney Hospital, High-street, Homerton, E.—Asst. M.O. £350.
Hereford, Herefordshire General Hospital. H.P. At rate of £150.
Hertford County Hospital.—Res. Surg. O. At rate of £250.
Hertford, County Sanatorium, Ware Park.—Asst. M.O. £300.
Hospital for Epilepsy and Paralysis, Maida Vale, W.—Hon. Dental S.
Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W. Asst. P.
Hospital for Sick Children, Great Ormond-street, W.C.—H.S., and H.P. Each at rate of £100.
Ilford, King George Hospital.—Asst. Res. M.O. £250. Also House Officer. £100.
Ipswich, East Suffolk and Ipswich Hospital.—Cas. O. £150. Also H.S. At rate of £120.
Inverness District Mental Hospital.—Jun. Asst. M.O. £350.
Inverness Northern Infirmary.—3rd Res. M.O. At rate of £100.
L.C.C.—Eighth Asst. M.O. for Mental Hospital Service. £445
Leicester City Education Committee.—Asst. School M.O. £500.
Leicester City, General Hospital.—Res. M.O. £250.
Lingfield Epileptic Colony, Surrey.—Asst. M.O. £225.
London Hospital, E.—Asst. Surgeon.
London Lock Hospital, 91, Dean-street, W.—Two H.S.'s. Each at rate of £200.
Maidstone, Kent County Ophthalmic and Aural Hospital.—Hon. Ophth. S.
Manchester, Ancoats Hospital.—H.S. At rate of £100.
Manchester and Salford Hospital for Skin Diseases.—H.S. £100.
Manchester Babies' Hospital, Burnage-lane, Levenshulme.—Jun. Res. M.O. At rate of £50.
Manchester City Education Committee.—Asst. School M.O. £600.
Manchester, National Radium Centre, Nelson-street.—Radium Reg. £350.
Manchester Royal Infirmary.—Jun. Asst. M.O. for Radiological Dept. £400. Also Dickinson Scholarship. £150.
Market Drayton, Salop, Cheshire Joint Sanatorium.—H.P. £250.
Merthyr General Hospital.—Res. H. S. At rate of £150.
Mildmay Mission Hospital, Austin-street, Bethnal Green, E.—Hon. Dental Surgeon.
Monmouthshire C.C.—Asst. M.O. £500.
Narborough, near Leicester, Leicestershire and Rutland Mental Hospital.—Locum Tenens. M.O. 7 gns. a week.
National Hospital, Queen-square, W.C.—Res. M.O. £200.
New Zealand, Christchurch Hospital Board.—Med. Reg. £500.
Northampton General Hospital.—Two Asst. H.S.'s. Each at rate of £150.
Northwood, Middlesex, Mount Vernon Hospital.—H.S. £200.
Oldham Royal Infirmary.—Two H.S.'s. Each at rate of £175.
Orkney, Island of North Ronaldshay.—Med. Man under Scottish Board of Health. £400.
Plymouth, City Hospital.—Res. M.O. £350.
Plymouth, South Devon and East Cornwall Hospital.—H.S. At rate of £100.
Portsmouth Royal Hospital.—Sen. H.S. At rate of £175. Also H.P., Two H.S.'s, and Cas. O. At rate of £130 and £100 respectively.
Preston and County of Lancaster Royal Infirmary.—H.S. and H.P. Each £150.
Princess Louise Kensington Hospital for Children, N. Kensington, W.—H.S. and Cas. O. At rate of £75.
Prince of Wales's General Hospital, Tottenham, N.—Sen. H.P.'s and H.S.'s. All at rate of £120. Also Jun. H.P.'s and H.S.'s. All at rate of £90.
Reading, Royal Berkshire Hospital.—Cas. O., and Res. Anæsthetist. At rate of £150.
Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—Two Res. Anæsthetists. Each at rate of £80.
Rowley Regis Urban D.C.—Temp. Half-time Asst. M.O.H., &c. £300.
Royal Free Hospital, Gray's Inn-road, W.C.—Asst. Physician.
Royal London Ophthalmic Hospital, City-road, E.C.—Sen. Res. O. £150.
Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Hon. Clin. Asst.
Salop County Council.—Asst. M.O. £600.
Shanghai Municipal Council, P.H. Dept.—2nd Asst. Commissioner of P.H. 650 Tls. per mensem.
Ryde, Royal Isle of Wight County Hospital.—Res. H.S. £180.
Sheffield Royal Hospital.—H.S. Also Ophth. H.S. Each at rate of £80.
South London Hospital for Women, South Side, Clapham Common, S.W.—H.P., and H.S. Each at rate of £50. Also Clin. Asst. to Surg. Out-patients.
Southampton Children's Hospital and Dispensary for Women.—Res. M.O. At rate of £100.
Southampton, Royal South Hants and Southampton Hospital.—Asst. H.S. At rate of £180.
St. Bartholomew's Hospital, E.C.—Asst. Dental Surgeon.
St. John's Hospital, Lewisham.—H.P., H.S., and Cas. O. Each at rate of £100.
St. Mary's Hospital for Women and Children, Plaistow, E.—Res. and Asst. Res. M.O.'s. At rate of £175 and £120 respectively.
St. Peter's Hospital, 74, Vallance-road, E.—Asst. M.O. £450.
Stafford, Staffordshire General Infirmary.—H.S. At rate of £200.
Sunderland, Durham County and Sunderland Eye Infirmary.—Two Ophth. Surgeons. Each £350.
Swansea Hospital.—H.S. £150.
Taunton and Somerset Hospital.—Sen. H.S. At rate of £150.
Walsall General Hospital.—H.S. At rate of £150.
Walsall, Manor Hospital.—Res. Asst. M.O. £200.
Weir Hospital, Grove-road, Balham, S.W.—Sen. Res. M.O. £200.
West London Hospital, Hammersmith, W.—Hon. Ophth. S.
West Riding of Yorkshire, Middleton-in Wharfedale Sanatorium.—Jun. Res. M.O. £250.
Western General Dispensary, Marylebone-road, N.W.—Hon. Ophth. Surg.
Western Ophthalmic Hospital, Marylebone-road, N.W.—Res. Sen. H.S., and Jun. H.S. At rate of £150 and £100 respectively.
Wigan County Borough Education Committee.—Asst. School M.O. £500.
Willesden General Hospital.—Two Clin. Assts.
Worcester, Besford Court Catholic Mental Welfare Hospital for Children.—Res. Med. Reg. At rate of £150.

ADDRESSES AND ORIGINAL ARTICLES

THERMAL ADJUSTMENT OF MAN AND ANIMALS TO EXTERNAL CONDITIONS.*

By Sir Charles J. Martin, C.M.G., M.B., D.Sc., F.R.C.P. Lond., F.R.S.,

DIRECTOR OF THE LISTER INSTITUTE OF PREVENTIVE MEDICINE; PROFESSOR OF EXPERIMENTAL PATHOLOGY IN THE UNIVERSITY OF LONDON.

LECTURE III.

In my last lecture I critically examined the evidence for diminution in resting metabolism in hot climates. The conclusion was that some people in hot climates reduce their resting metabolism 10 per cent. As, however, a reduction of 10 per cent. on resting metabolism, even if it continued during activity, would only amount to 2 per cent. when walking four miles an hour, its effect on anything except a vegetative life is insignificant.

On Heat Regulation in a Warm Environment.

When the environmental temperature approaches or exceeds that of the body, the only adjustment available is to rid the body of the heat formed by the evaporation of water. The amount of heat lost by evaporation from the upper respiratory passages is not inconsiderable, and is the principal means of refrigeration employed by a dog. A man working hard and breathing, say, one cubic foot per minute of air at a temperature of 97° F. and half-saturated with moisture, would lose by evaporation—assuming that the expired air were saturated at this temperature—0·43 g. of water in a minute, or 0·25 large calories in heat. These calories would, however, be but a 5 per cent. contribution to the loss of heat required in the case of a man at work or walking four miles an hour under the above circumstances. The rest must be lost by evaporation from the surface of the body.

Water arrives at the surface of the skin (1) by the imbibition of water by the epidermis from the moist cutis; (2) by the active secretion of sweat. It does not seem possible to express the imbibed water from epidermis, even by considerable pressures. I have tried to press liquid through skin from within outwards, using a pressure of two atmospheres. None passed through in 24 hours, unless the epithelial covering were defective. When an area of epithelium was removed leakage occurred, just as serum exudes from an abrasion of the epidermis during life.

Epidermis is composed of hydrophile proteins spread in a layer of 0·1 to 0·5 mm. thickness upon the cutis. It imbibes water from below and loses it from its free surface, although evaporation does not occur so readily from it as from a piece of wet rag. Only water molecules pass through the epidermis by transpiration, and salts do not accumulate on the surface as after sweating. Viale (1918) demonstrated experimentally that epidermis is impermeable to sodium chloride, and Hancock, Whitehouse, and Haldane (1929) found that, unless sweating occurs, the amount of salt that can be washed from the skin of a man unbathed for a week is trifling, although many litres of water must have passed by transpiration. In a normal person it is difficult to determine how much water is lost by transpiration alone, because the sweat glands begin to contribute without obvious sweat, but Loewy and Wechselmann (1911) were able to determine in two persons with congenital absence of sweat glands that 217 and 460 c.cm. respectively were transpired in 24 hours. Taking the higher figure, this would amount to a loss of 0·18 calories per minute. This would be quite inadequate to rid the body of heat when it had to depend on evaporation alone, and persons without sweat glands are obliged to avoid both heat and activity unless they wear a wetted shirt. That imbibition is enough to keep the epidermis from drying up is clear from the fact that most animals have no sweat glands over the greater part of their bodies, and from the observations of Zuntz and Tendau (1901) and Loewy and Wechselmann (1911) on persons with congenital absence of sweat glands. Imbibition will, however, never produce a damp skin.

The Conditions which determine Sweating.

As long as the skin is cool the activity of the sweat glands is in abeyance, but, as Anbert (1877) and Schwenkenbacher (1903) showed, it must not be assumed that because no sweat is obvious to the naked eye there is no secretion. By using either Anbert's or Jurgensen's (1924) method, a minimal secretion can be demonstrated, and I find that, in my own case, the sweat glands come into operation very gradually as my skin warms, and a sudden outpouring of sweat does not occur until the body temperature has appreciably risen. The most effective stimulus is a rise in the temperature of the blood-supply to the brain, and the easiest way to make a man sweat is to make him hyperthermic either by exercise or hot baths. The local temperature of the sweating part also has an influence.

The relative importance of local warmth and central thermal stimulation in the normal outpouring of sweat is difficult to assess, but the experimental evidence points to the latter as more essential. Filehne (1910) says that in a bath of 41° C. sweating began on the forehead before he could detect any rise in the rectal temperature, and ceased on plunging the hand into cold water. This he interprets as sweating following a generally warm skin inhibited by a stimulus of cold from a limited area. Leonard Hill (1921) made a similar experiment on himself in a room at 40° C. with the same result. When, however, he prevented the return of blood from the cooled limb by a rubber cuff, sweat did not cease over the rest of the body. He concluded, therefore, that the effect of plunging the hand into cold water was to add some cool blood to the general supply and so lower the blood temperature. E. Cramer (1890) and also Kittsteiner (1916) have endeavoured to analyse the relative effects of body temperature and local temperature on sweating. They enclosed one or both arms in air-tight vessels for the collection of sweat. The arms enclosed in the vessels could be immersed in baths of different temperatures, whilst at the same time the body temperature was raised by sitting in a hot room. When the temperature was raised enough to cause visible sweating over the surface generally, the cold arm sweated less than the warm arm. If sweating was profuse, the temperature of the vessels in which the arms were immersed had to be lowered to 10° C. to inhibit sweating, and sweating from the

* The Croonian Lectures delivered before the Royal College of Physicians of London on June 12th, 17th, and 19th. Lectures I. and II. appeared in THE LANCET of Sept. 13th and 20th respectively.

rest of the body ceased soon after. There seems, therefore, no doubt that the activity of the sweat glands is more readily called forth by direct stimulation of the sweat centre in the front of the *tuber cinereum* (Hasama (1929)) when the skin is warm, for if the skin is cold the inhibition of the centre must first be overcome. On the other hand, many individuals sweat from the forehead before a rise in body temperature occurs.

MATERIAL LOST TO THE BODY BY SWEATING.

I do not propose to enter into the composition of sweat, beyond pointing out that the sodium chloride present varies from 0·05 to 0·4 per cent. and accounts for about 80 per cent. of the inorganic constituents. According to Kittsteiner (1911), at the commencement of sweating the organic constituents preponderate, but as sweating becomes profuse the salts increase and ultimately exceed the organic substances, which gradually decrease. From the point of view of the effect of hot surroundings upon health, the organic constituents do not signify, but the amount of salts is not immaterial, for with the profuse sweating necessary to enable a man to work in hot climates or hot environments—such as stokers and miners often have to endure—enough inorganic salts may be removed from the body to cause trouble, since the water lost is usually replaced with ordinary water. I have calculated how much sodium chloride may be lost to the body in 24 hours, from data on the quantity of sweat secreted given by Moss (1923) and Hunt (1912). It seems that this may sometimes amount to 10–20 g. per day.

This subject has recently been illuminated by the researches of Moss (1923), and particularly by those of Hancock, Whitehouse, and Haldane (1929), who have shown that miners' cramp is due to "water-poisoning," and can be obviated by drinking 0·2 per cent. sodium chloride solution instead of water. In this respect, it is interesting to recall that some years ago Elliott (1908) recorded that the best means of treating miners' or stokers' cramp was with saline enemata. Moss records that miners working in an atmosphere of which the wet bulb temperature was 85° F., lost on an average two pints of water per hour by sweating, the maximum being 4½ pints. I understand from Hunt that a coolie can lose 10 per cent. of his weight, that is twice the volume of his blood, without ill-effect.

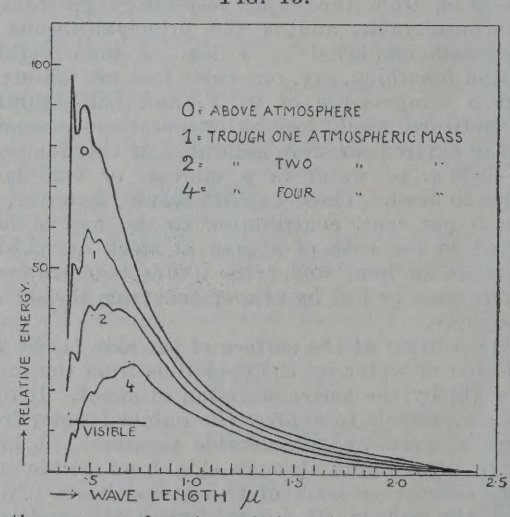
One would anticipate that, with all this outpouring of water through the skin, the blood would become more concentrated. As a matter of fact, the opposite occurs Gross and Kestner (1919), Cohn (1919), Eckert (1920), and Barbour (1924) have shown that with the onset of sweating there is a flow of water, salts, and proteins from the tissues into the blood stream, and the blood becomes richer in plasma and poorer in corpuscles. When sweating is profuse and prolonged, the water derivable from the muscles and the other tissues approaches the limit, and the blood concentrates. When this occurs the secretion of sweat diminishes and the individual is in danger of hyperthermia.

Sunshine and Heat.

The Contribution of Sunshine to the Thermal Profit and Loss Account.—It is common experience that sunshine with a low air temperature is grateful and comforting, but if the external temperature is high it becomes oppressive. Especially is this the case if hard muscular work has to be accomplished. The calorific value of the sun's radiant energy as it arrives at the outer limit of the atmosphere was determined by Abbot (1908) to be about 2 gramme-calories per sq. cm. per minute and the diminution of energy by passag through the atmosphere of different degrees of hazine and at different zenith angles, can be measured; bu just how much of this energy is absorbed by the huma body and added to its total balance of heat has onl been guessed at. Rubner and Cramer (1894) realise that it was considerable, and equivalent in effect t raising the air temperature from 25° C. to 33·5° C.

I have, during the last few years, been endeavourin to fill the lacuna in our knowledge. This is a heart breaking climate for work requiring a steady incidenc of sunlight; few days in the year are suitable, an on many of those days something happened to preven me from availing myself of the heaven-sent oppor tunity. Consequently, progress was slow. Fig. 1 represents how the total radiant energy of the su is partitioned amongst radiations of different wave length; it is borrowed from Abbot (1908). Th region of the visible spectrum, λ 390–770, is indicated It accounts for about 60 per cent. of the sun's energ above the atmosphere and 50 per cent. by the tim it reaches the earth. When the sun is in the zenit there are no radiations shown of wave-length shorte than λ 0·38μ in the near ultra-violet, nor longer tha 2μ in the infra-red, the reason being that Abbot' apparatus involved the use of glass; but 99 per cen of the total energy of the sun passes through glass The spectrum of the sun does indeed extend t

FIG. 13.



Relative energy of sun's radiation at different wave-length (O) as it reaches the earth's atmosphere (1), (2), (4), after passing vertically through one, two, and four atmospheric masses (zenith angle 0°, 60°, and 75° respectively). From observations by Abbot (1908).

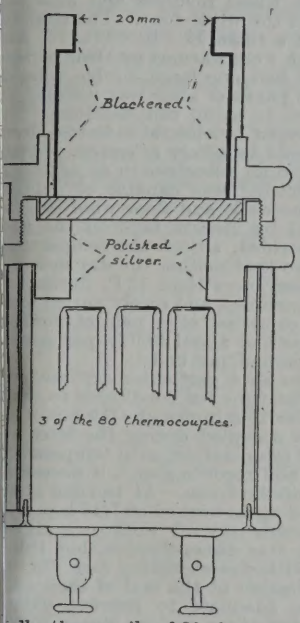
λ 0·29μ and it is these small wave-lengths which possess such high biological significance—e.g., in causing sun-burn and pigmentation and in the prevention or cure of rickets by the activation of ergosterol and formation of vitamin D. Their energy value is, however, small, and amounts to but a fraction of 1 per cent. of the total energy.

The chart also indicates how the energy of the sun is differentially absorbed as it passes through more and more of the atmosphere. Curve 0 represents the distribution of energy at the outside of the earth's atmosphere; Curves 1, 2, and 4, when it has passed through one, two, and four atmospheres respectively, the last two being obtained by taking observations at increasing zenith angles.

When radiations impinge upon a surface, a portion is absorbed and changed into heat; the rest is

eflected. I was concerned to determine the proporion of the total radiant energy absorbed by the uman skin, but, being enable to do this, I had to neasure the amount which is not absorbed but diffusely reflected. The difference gives the result required. To this end I used a sensitive thermopile in which the thermocouples were shielded from draughts by a glass window. It had 80 blackened thermocouples spread out over a circular area of 300 sq. mm. The general structure is seen in Fig. 14. The thermopile was in circuit with a sensitive microampèremeter, and the deflection of the galvanometer (not shown in the diagram) is proportional to the energy absorbed by the couples, which is about 98 per cent. of the radiant energy impinging upon them. In making the observations, the thermopile was momentarily presented to the sun and the deflection of the galvanometer read; the thermopile was then esented to the skin or clothing of an individual minated by the sun, and a second reading taken. number of readings of sun and reflected energy re made, noting each time the altitude of the sun. ving obtained these values some calculations had be applied to them.

FIG. 14.



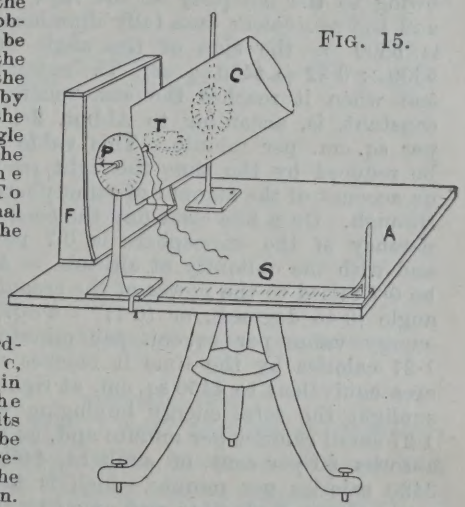
olls thermopile of 80 thermocouples (scale 9/10th) with blackened projection as employed in the experiments described in text.

The sun's rays being parallel and my pile correctly nted, the pile absorbed the whole energy of a beam sunlight, of which the sectional area corresponded the circular aperture of 314 sq. mm. in the pile, the diffusely reflected rays from the skin are ttered in every direction, and to gather into my rmopile an amount equivalent to the rays scattered m a surface of skin illuminated by a beam of light 314 sq. mm. in area, I should have to her the reflection from a flat surface similarly minated of infinite extent. This is impracticable. e largest more or less flat area of skin available a man's back is less than a foot square. It was essary, therefore, to have a projecting cylindrical e, blackened inside, in front of my thermopile own in Fig. 14) to reduce the solid angle of aperture, that at 10 cm. distance it would be completely d by light reflected from less than a square foot skin. The next difficulty was to ascertain the o of universally scattered radiations picked up by thermopile to those it would pick up if its solid le of aperture were 90 degrees, and it were exposed an infinite surface. This problem was entirely ond my capacity, but I was fortunate enough to st the sympathy of Professor E. A. Milne, F.R.S., xford, who found a solution for me. His mathetical reasoning is beyond my comprehension. He published the general solution in the *Philosophical Magazine* for February, 1929, showing that is the solid angle of aperture of my thermopile, ratio sought is $tan^2 \frac{\theta}{2}$.

Knowing the solid angle of aperture of my thermopile, I was now equipped with a factor to apply to my measurements of the energy picked up by my instrument from the limited area of skin filling its aperture, and so could arrive at the proportion diffusely reflected.

Fig. 15 shows the apparatus used. The solid table was adjusted to be horizontal. Its top was capable of rotation in a horizontal plane to follow the sun, alignment being indicated by the shadow of the upright, A, to the right of the picture on the scale. The length of the shadow on the scale, S, measured the altitude of the sun. The thermopile, T, enclosed in the cardboard screen, C, and shown in dotted outline, can be rotated on a horizontal axis at right angles to the scale. Attached to it is a pointer, P, which travels over a circle graduated in degrees. Supposing the length of the shadow indicated the sun's altitude at the moment to be 50°–10′, the pointer was moved to this reading on the circle and the front of the pile then pointed to the sun. To the left of the table a stout vertical wooden frame, F, is shown. Aginst this frame the back of the subject was rested and arranged to be as flat and vertical as was consistent with his anatomical peculiarities. For the examination of fabrics the vertical alignment could be secured by stretching them on a board applied to the frame. To obtain a reading of the energy reflected the pile was rotated so as to be at right angles to the surface examined, as shown by the position of the pointer P. The amount of deflection of the galvanometer observed had to be corrected for the obliquity of the illumination by dividing it by the cosine of the angle of altitude of the sun at the moment. To avoid additional illumination of the surface under examination by skylight, the thermopile was enclosed in a hollow cardboard cylinder, C, about a foot in diameter. The inclination of its axis could be varied to correspond with the altitude of the sun.

FIG. 15.



Horizontal rotating table (about 1/12th scale) showing arrangements described in text for "shooting" the sun and pointing the thermopile at right angles to the skin. The thermopile T is enclosed in a cardboard cylinder C so that the skin shall not be illuminated from the sky.

Before experimenting with human skin I made measurements with a particular sample of white blotting paper until I had surmounted many technical difficulties and could obtain consistent results on different days, whatever the altitude of the sun. The following table summarises the results I obtained:—

Material.	Percentage of sun's energy diffusely reflected.	Percentage absorbed or passed.
Blotting-paper	78	22
White cotton shirt, two thicknesses, unstarched	71	29
Khaki cotton shirt	43	57
Dark grey flannel suiting ..	12	88
Dress suit	5·5	95
Black velvet	3·2	97
Skin, fine white	45	55
,, average blonde	43	57
,, dark, brunette (Semite) ..	35	65
,, ,, ? some negro blood ..	30	70
,, ,, Hindu	22	78
,, ,, Negro	16	84

The amount regularly reflected from skin is not great, but I have not been able to determine this accurately. In the case of a piece of shiny brown wrapping paper, more shiny than skin, I was surprised to find it was only 3·3 per cent. of the total incident light.

We are now in a position to answer the question: how much energy in heat units a man may absorb when exposed to the sun? This will obviously depend upon the amount of surface illuminated. With a vertical sun a man lying down exposes much more surface to the sun's radiation than when standing up. With a nearly setting sun the result will be reversed. It will also depend upon the obliquity of the illuminated surface, the amount of atmosphere the sunlight has traversed, and the haziness of that atmosphere. For all these reasons we can only deal with a concrete instance. Suppose the sun be at an altitude of 55 degrees, which is about what it is in June in London for an hour or two around mid-day. At this altitude I happen to know that my shadow, standing erect and naked, is 5500 sq. cm. The illumination of this area is, however, attenuated owing to the obliquity of the rays to the vertical, and the equivalent area fully illuminated by the sun is 5500 × the sine of the angle of altitude, or $5500 \times 0{\cdot}82 = 4450$ sq. cm. The radiant energy of the sun when it reaches the atmosphere, or the solar constant, is, according to Abbot, 2·1 small calories per sq. cm. per minute. This value will, however, be reduced by the time the light reaches my body on account of the amount of atmosphere it has passed through. On a fine clear day the coefficient of transparency of the atmosphere is 0·7 per atmosphere, and with the obliquity at altitude = 55 degrees will be 0·7 raised to the power of the secant of the zenith angle (0·45 degrees), or $(0{\cdot}7)^{1{\cdot}4} = 0{\cdot}607$, so that the energy value per sq. cm. per minute will be but 1·27 calories by the time it reaches me. With an area equivalent to 4450 sq. cm. at right angles to the sunlight the total energy impinging will be 4450 × 1·27 small calories per minute and, as my naked skin absorbs 60 per cent. of sunlight, $4450 \times 1{\cdot}27 \times 0{\cdot}6 = 3420$ calories per minute, which is three times my resting heat production and equal to the amount of extra heat I should produce by walking three and a half miles per hour on the flat.

Work and High External Temperature.

The amount of work a man can do under temperate climates depends upon the muscular development and skill of the individual and the amount of oxygen he can bring to his muscles in unit time; in other words, his respiratory and circulatory capacity. At high temperatures these factors operate, but the limit of accomplishment also depends upon the rate at which he can get rid of the heat inevitably formed. This involves a good deal of work upon the heart, so that the efficiency with which external work can be performed depends upon the climatic conditions. Some years ago, in 1913–14, I set out to try to determine whereabouts this climatic limitation was situated in my own case. To this end I decided to keep the work at a constant level and chose a rate of work equivalent to 1/10 h.p. which, I understood from my engineering friends, was what they considered to be the output of a good labourer during hard manual work. It has since emerged from the observations of Moss (1923) upon the oxygen utilisation of a hard-working miner, first, whilst heaving coal and subsequently working upon my bicycle ergometer until he consumed the same amount of oxygen, that I was very nearly correct in my choice of 3300 ft. lb. (456 km.) per minute as a standard of economi performance.

To measure the work accomplished I designed a simp form of bicycle brake-ergometer. The tension on the brak band could be set to give any desired rate of work and has the merit of not changing its coefficient of friction wit the velocity with which the wheel revolves and does n require an assistant to record the work done. The climat conditions were produced in a room 12 × 10 × 9 ft. It ha three inside walls, all of which were warmed on their outsi by adjustable radiators. It had one large double windo and the air between the two panes of glass was warmed b a long coil of resistance wire, to avoid condensation. Th interior of the room was warmed by electric radiators, fro which the output of heat could be nicely adjusted. Stea was introduced by a pipe from an autoclave in an adjoinin room and the quantity admitted was capable of delica adjustment from inside. The walls and floor were cover with felt and the air mixed by electric fans on the flo at the corners. I could, unaided, adjust the temperatu and humidity of this room, so that neither the dry bulb n wet bulb thermometers varied more than 1° F. during t three or four hours of an experiment and rarely varied mo than 0·5° F. My clothing consisted of a pair of runnin pants and I had an air current of about 250 ft. per minu impinging upon the upper part of my body.

Having arranged the room at a particular dry and w bulb temperature and allowed time for conditions to sett down, I proceeded to work for 15 minutes at 1/10 h.p. × 4/ I then dismounted and was occupied during the next fi minutes in taking my rectal temperature, skin temperatu pulse- and respiration-rate, and recording and, if necessar adjusting the temperature of the room. At the end of t five minutes I remounted and again worked at 1/10 h.p. × 4 for another 15 minutes. In this way my work over all w at the rate of 1/10 h.p. It was discontinuous, but this usual in manual labour. With one exception (see Fig. 1 I did not increase my respiration at the end of each spe so my cardiac output was adequate to prevent oxyg debt. The experiments lasted three or four hours, duri which, if thirsty, I drank some weak tea without milk sugar. The results will be apparent from the two cha (Figs. 16 and 17) in which rectal temperature is plott against time.

It will be seen from the charts that the rect temperature varies at the commencement of t observations. This is because, in the severer climat conditions, the light work involved in arrangi the experiment and adjusting the temperatures the room to the desired points made me slightly hype thermic. During the first working hour the bo temperature rose, ultimately coming into adjustme at varying levels, according to the severity of t conditions, and remaining so during the whole of t period. I sweated profusely, losing 1 to 2 lb. in weig per hour after the initial warming up. The maxim wet bulb temperature I could endure under these co ditions was 87° F. (see Fig. 16), and it did not see to make any difference to me whether the simultaneo dry bulb was 86° or 101° (Fig. 17). This suppo Haldane's (1905) contention, from experiments up himself and Boycott, sitting in a hot room, that wh heat regulation has to depend almost entirely up sweating the effect of the temperature of the d bulb is immaterial.

The upper curve in Fig. 17 illustrates wh happened when I failed in adjustment, but st continued working at the same rate, as long as dared. You will notice that at the time I desist my temperature had risen to nearly 103°, pulse 15 and respiration 48. I felt a palpitation in my ne and throat and increasing incapacity for effort, b after a few minutes' rest, still at a dry bulb temperatu of 98° and wet bulb of 88°, my respiration and pu slowed down and the body temperature soon aft returned to a reasonable level. It is surprising wi what suddenness these symptoms occur. If a subj cannot adjust for a body temperature of 103° F. is in a vicious circle, for as the body temperature ri the heat formation, independently of work, also ris Harvey Sutton (1909) found that even when reposi in a chair in a hot room his gaseous metaboli

increased 50–100 per cent. when his rectal temperature reached 103·5° F. The breakdown in my case appeared to be entirely circulatory. In the effort to facilitate loss of heat, more blood is diverted to the skin, and unless the minute volume of the heart can be increased to compensate for this divergence there is not enough oxygen supplied to the muscles to prevent oxygen debt. Once this occurs it soon becomes impossible to carry on at the same rate of work.

That a rise of 1–3° F. occurs with exercise, even when there is no great strain put on thermotaxis, is so universal that Zuntz and Schumberg (1901) and Pembrey (1913) suggest that it is a physiological adaptation rather than a failure of compensation; much of the transference of heat by evaporation takes place too far from the capillary loops wherein the blood to be cooled circulates, and a proportion of the heat absorbed by evaporation will be derived from the air and surrounding objects instead of from the body.

In my experience the obstacle to work in hot climates is, for the European, as much a social as a physiological one. It is clothing. The coolie works with his nice brown body exposed and covered with sweat, and is jolly, whereas the white man distressfully labours in a hyperthermic condition, straining his heart to work a refrigerating plant which he has rendered inefficient because his sense of dignity forbids him to expose his skin.

FIG. 16.

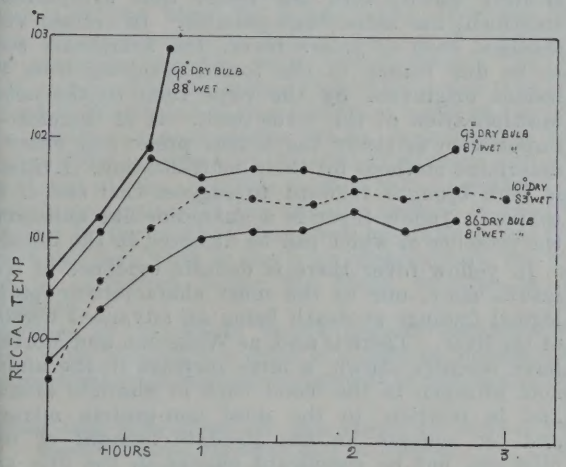


FIG. 17.

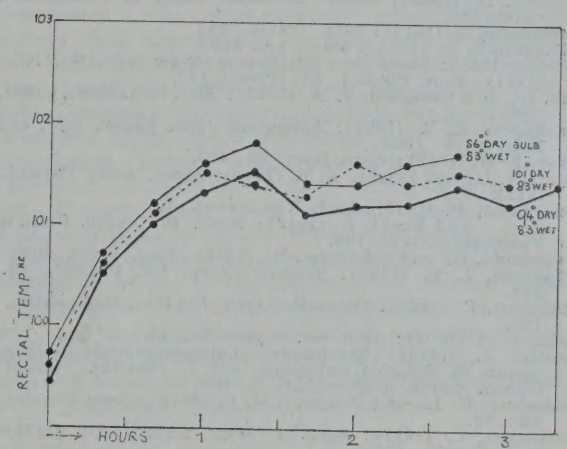

Influence of working at 1/10 h.p. (456 kilogramme metres per minute), under different atmospheric conditions, upon body temperature.

with this I agree. Every physiological process works quicker a little above average body temperature and oxygen is more readily dissociated from hæmoglobin, but I think another advantage is that with a slightly raised temperature the same amount of heat can be got rid of per minute without diverting so much of the blood to the skin.

Work in hot surroundings demands a stout heart. The individual has to do not only the external work demanded, but also to run a refrigerating plant to rid him of the heat inevitably formed. That, no doubt, is why young vigorous persons do best in warm climates and why breakdown of thermotaxis is particularly likely to occur when weary towards the end of the day. Walking at four miles an hour requires about the same oxygen consumption as performing work at 1/10 h.p. on the ergometer so that it produces the same amount of heat. What this amounts to in heat output per minute is readily calculated: 1/10 h.p. is 3300 ft. lb. per minute, or 456 kilogram metres. As the efficiency of a man is not more than 20 per cent., four times this amount of energy is liberated in the form of heat. The equivalent of 1842 km. is 4·35 large calories which, added to an average resting heat production, makes about 5·5 large calories. I have already indicated that if the work is performed in the sun another four or five calories may have to be added to the amount of heat to be removed per minute. In a climate the shade temperature of which is at or above that of the skin, ten large calories have to be removed by evaporation of water. This would require the evaporation of a litre an hour even when the whole of the heat to do this is derived from the body. If clothes are worn, unless very thin and wet,

GUANIDINE-LIKE SUBSTANCES IN THE BLOOD IN EXPERIMENTAL YELLOW FEVER.

By G. M. Findlay, O.B.E., D.Sc., M.D. Edin.,
AND
E. Hindle, Sc.D. Camb., Ph.D.,
BEIT MEMORIAL RESEARCH FELLOW IN TROPICAL MEDICINE.
(*From The Wellcome Bureau of Scientific Research, London.*)

THE specific chemotherapeutic treatment of diseases due to ultra-microscopic viruses has, up to the present, entirely failed, with the result that symptomatic treatment has alone been possible. In certain virus diseases, such as yellow fever, the symptoms seem to be due rather to the toxins resulting from the lesions originated by the virus than to the actual multiplication of the virus itself. It is therefore of importance to study the toxins present in order to determine methods for their neutralisation. Evidence is here brought forward to suggest that one of the toxins in yellow fever is a guanidine-like substance, the presence of which can be detected in the blood.

In yellow fever there is definite evidence of liver insufficiency, one of the most characteristic pathological findings at death being an advanced necrosis of the liver. There is also, as Wakeman and Morrell [1] have recently shown, a large increase in the amino-acid nitrogen in the blood both in absolute amount and in relation to the total non-protein nitrogen and an increase in the absolute amount of urea nitrogen, but no significant change in the uric acid concentration of the blood. Blood creatinine is only slightly increased. Now the observations of Minot and Cutler [2] in 1928 showed that in liver necrosis brought about by carbon tetrachloride or chloroform, there occurs an increase in the guanidine or guanidine-like substances in the blood. More recently the same workers [3] have determined a similar increase in guanidine-like substances in eclampsia and in the liver necrosis associated with arsphenamine poisoning, while Ellsworth [4] has this year reported similar findings in six cases of arsphenamine jaundice, five cases of Laennec's cirrhosis of the liver and one case of Banti's disease. Guanidine estimations of the blood in five patients with hæmolytic or obstructive jaundice fell within the normal range.

Since there is an increase in guanidine-like substances as the result of poisoning by compounds such as carbon tetrachloride and chloroform it is of interest to note that these intoxications are characterised by nervous hyperexcitability, followed by depression, and by a gastro-intestinal irritation evidenced by vomiting, diarrhœa, and frequent hæmorrhages. Now there is not lacking evidence that these symptoms are due, at least in part, to intoxication with guanidine compounds. Frank, Stern, and Nothmann,[5] for instance, in 1921, recorded the following symptoms in dogs as the result of poisoning with guanidine compounds—tremor, restlessness, hoarse barking, salivation, vomiting, diarrhœa, apathy, weakness, and death. Minot and Cutler noticed fibrillary twitching of muscles, with more or less severe tetanic convulsions followed by extreme depression, weakness, and death. Vomiting was common and the vomitus was often bloody. At autopsy the pyloric end of the stomach and upper third of the small intestine showed extreme congestion

th many small hæmorrhagic areas. This is the ea in which, according to Carter,[6] hæmorrhages e constantly found in yellow fever in man. It ll thus be seen that there are certain similarities tween carbon tetrachloride poisoning, guanidine isoning, and yellow fever.

In addition the changes in the blood-sugar are nilar in character in the three conditions, for Minot d Cutler[3] have reported hypoglycæmia in carbon rachloride and guanidine poisoning, while iczynski,[6a] Gomes,[7] and Wakeman and Morrell[1] have ınd a quite definite decrease in the blood-sugar in llow fever both in man and monkeys.

Observations on Monkeys.

It appeared to be of interest therefore to determine ether there was an increase of guanidine-like ostances in the blood in yellow fever. For this rpose observations were carried out on *Macacus sus* monkeys infected with yellow fever. The thod employed in the earlier observations was that scribed by Major and Weber[8] which is based on the our reaction for guanidine bases described by gs[9] in 1924, modified by Marston,[10] Pfiffner, and ers,[11] and others. By this method it is necessary make a correction for the creatine present in the od, but in the method described by Pfiffner and ers,[12] and here used in the later observations, the of a correction factor for blood creatine is necessary.

Reference to the table shows that in monkeys ected with yellow fever there is a definite increase the guanidine-like substances present in the blood.

*No fever.

ow Minot and Cutler[13 2 3] have emphasised fact that calcium salts have a highly protective on in preventing and treating intoxications ciated with an increase in the guanidine base ent of the blood, at the same time raising the d-sugar. It was, therefore, hoped that the inistration of calcium lactate to monkeys with ow fever would have some curative action; con- ently 5 c.cm. of a 5 per cent. solution of calcium ate were given to monkeys with yellow fever, peritoneal injections being given at intervals of hours. Such injections of calcium lactate oubtedly reduce the amount of guanidine-like substances present in the blood, as shown by the following protocols:—

MONKEY 346, suffering from yellow fever: 9 A.M. guanidine bases in blood, 0·400 mg. per 100 c.cm. of blood; 11 A.M. 5 c.cm. of 5 per cent. solution of calcium lactate injected intraperitoneally; 1 P.M. guanidine bases in blood, 0·251 mg. per 100 c.cm. of blood; 6 P.M. guanidine bases in blood, 0·498 mg. per 100 c.cm. of blood.

MONKEY 359, suffering from yellow fever, 2nd day after inoculation: 10 A.M. guanidine bases, 0·421 mg. per 100 c.cm. of blood; 10 injections of 5 c.cm. of 5 per cent. solution of calcium lactate and 2 per cent. glucose then given at intervals of 4 hours till 7 P.M. on the following day; 10 P.M. moribund, guanidine bases, 0·262 mg. per 100 c.cm. of blood.

Unfortunately, calcium lactate, even when injected with glucose, does not appear to have any action in preventing the final collapse and death in monkeys suffering from yellow fever, despite its action in reducing the guanidine-like substances in the blood. Nevertheless, the post-mortem examination of monkeys thus treated has revealed one interesting fact. While the necrotic condition of the liver is similar to that found in control monkeys, the animals (8 in number) treated with calcium lactate have all exhibited a freedom from gastro-intestinal and pulmonary hæmorrhages, lesions which are usually found in 60 per cent. or more of monkeys dying from yellow fever. Consequently, there is some evidence that the hæmorrhages in yellow fever may be controlled by the administration of calcium lactate, which may therefore be of use in the treatment of human cases of yellow fever. It should be emphasised that the effect of the calcium in reducing the amount of guanidine-like substances does not last for more than a few hours, as shown in the experiment recorded above. Repeated injections of calcium at short intervals are therefore indicated.

In view of the extremely low blood pressure, possibly associated with the presence of toxic amines in the blood, it seems not improbable that the intravenous injection of saline or of gum arabic as used in the treatment of surgical shock would also be of value in the treatment of yellow fever in man.

Conclusions.

(1) In experimental yellow fever in monkeys there is an increase in the blood content of guanidine-like substances, similar to that associated with other conditions involving liver necrosis. (2) The increase in guanidine-like substances can be reduced by the administration of calcium lactate. (3) Calcium lactate does not prevent death in monkeys suffering from yellow fever but does tend to prevent hæmorrhages.

CONGENITAL ARTERIOVENOUS FISTULÆ.

By Dean De Witt Lewis, M.D. Illinois,

SURGEON-IN-CHIEF TO THE JOHNS HOPKINS HOSPITAL, BALTIMORE, AND PROFESSOR OF SURGERY IN THE UNIVERSITY SCHOOL OF MEDICINE.

(*Concluded from p. 628.*)

It is difficult to determine whether or not some of the early cases should be classified as congenital arteriovenous aneurysm, for the clinical and pathological data are not abundant. Short abstracts will be made of the history of the cases which can properly be regarded as congenital arteriovenous aneurysm, and the results of the treatment of these then analysed.

History of Reported Cases.

Letenneur, 1859.—Patient was a man of 43 years, who, when 7 and 22 years of age, bled profusely from an injury of his right ring finger. The lesion involved the hand and forearm, extending up to the elbow. An amputation of the arm had to be done finally because of hæmorrhage.

Krause, 1861.—Male, aged 33. When 8 years old a vascular tumour was noted in the palm of the left hand between the index and middle fingers. Finally the hand and forearm became involved. Atrophy of the finger developed. Pain developed and became so intense that the arm could not be used. The extremity was 1½ inches longer than the right. A dog bit the patient in this hand when he was 26. This had no relation appearently to the vascular lesion. Compression was tried as a curative procedure, but had to be given up because of the discomfort it caused. Finally an amputation of the arm was performed. An abnormal communication was found between the median artery, a branch of the ulnar, and the digital arteries and veins.

Gross, 1867.—Female, aged 43. Patient was admitted to the hospital with an enlargement of the left foot and leg from back of the toes to as high as the knee. The vessels were dilated and pulsated. A thrill and bruit could be felt and heard over the vessels. An ulcer the size of a shilling was present on the dorsum of the foot. This bled occasionally. This would heal when the foot was elevated. A nævus maternus was present when she was born. The superficial veins and arteries became tortuous and increased in size at the age of 3 years. Six years later the ulcer appeared near the web of the great toe, and about four years before her admission to the hospital ulcers developed on different portions of the foot, the largest being over the internal malleolus. An attempt made at one time to ligate the femoral artery was unsuccessful, although two arteries were apparently ligated at the inner and upper portion of the leg. Subsequently, the leg was amputated below the knee. The internal saphenous vein was dilated and tortuous, with thickened coats, resembling an artery. The vessels of the amputated leg were injected with tallow and magnesia. The injection was made through the posterior tibial artery. The injection mass passed not only into the superficial and deep veins and arteries, but escaped from the medullary canal of the tibia and fibula. The posterior tibial artery was nearly as large as the femoral, and the accompanying veins were tortuous and nodular. The posterior tibial was the only artery that could be identified in the specimen. No mention made of the bradycardiac reaction or cardiac changes.

Hewett, 1867.—Sarah R., aged 17. The mother stated that when the child was born her right thigh was larger than the left, and the veins of the extremity were dilated. The girl stated that as long as she could remember there had been a peculiar beating in the leg. At first the swelling was confined to the thigh, but it soon extended into the leg and finally to the foot. This caused her little inconvenience unless she walked some distance or stood for a long time. Then the veins became much larger. Later some of the veins near the ankle had broken, and for this the patient came to the hospital.

Examination.—The right lower extremity was much enlarged, being increased not only in circumference, but it it was at least two inches longer than the left. The superficial veins were much dilated, and appeared as large, convoluted and tortuous cords under the skin. They were soft and compressible. The femoral vein was much enlarged and a distinct vibratory thrill could be felt. This could be trac up to the junction of the two iliac veins, but no thrill co be felt in this. A very loud, continuous-blowing murm could be traced up the vein to the same spot. A loud syst murmur could be heard at the apex of the heart. On lower part of the outer side of the leg was a large crust at point where bleeding had ccurred.

Operation.—A few days after admission to the hospi hare-lip pins were placed under all the veins which could seen running in the direction of the point of hæmorrha The vessels were then compressed by a twisted suture pla over the needle. The needles were allowed to remain 28 days. They caused very little irritation, but gradua produced thrombosis of the veins. The patient wh discharged was in much the same condition as when admitt the thrill and bruit remaining the same.

There was no history of trauma in this case, nor of dise which might account for a spontaneous arteriovenc fistula. The fact that the thrill and bruit terminated abrup where the common iliac artery (on the right side) lies up and crosses the common iliac vein, appears to indicate t point where the communication existed. The enlargeme and lengthening of the extremity and the dilated veins—noted at birth—indicate the congenital origin of the lesio

Gherini, 1867.—Girl, aged 9½. When the child was months old it was noted that the left hand was warmer a larger than the right. When the child was two, a tum appeared on the dorsum and palm of the left hand. T veins of the hand and forearm were greatly dilated. T tumour was treated by compression. At 7 years the tempe ture of the left hand was distinctly elevated. A tumour size of a florin appeared on the dorsum, and a sma one on the palm of the hand. These disappeared as result of direct pressure and compression of the brach radial, and ulnar arteries. They reappeared when press was removed. Pulsation could be distinctly seen, and a b heard. The veins of the hand and forearm were m dilated. The brachial artery was enlarged and tortuo Gherini regarded the lesion as a congenital aneurys varix. He successively ligated the radial and ulnar arter The symptoms, although less pronounced, persisted after ligation. The lesion remained about the same and did seem to progress.

Obalinski and Browicz, 1874.—Jewess, aged 30, for e years had noticed a vascular tumour in the left hand forearm which has increased, especially after each pregna This had been regarded as racemose angioma. Bleeding v gangrene of the finger occurred An amputation through arm was performed.

Nicoladoni, 1875.—17-year old male, shoemaker. genital vascular tumour of the right hand and finger. increased in size when the patient was 9 years of age, finally reached to the supraclavicular region. Ves most marked in the arm, where they showed distin through the skin. There was a decided increase in le of the extremity, and an increase in circumference u 5½ cm. when the arm was permitted to hang down. circumference was reduced by compression. Of spe interest in this case are the cardiac changes and the p reaction.

This is apparently the first case in which the car changes and the bradycardiac reaction are noted. apex-beat is recorded as diffuse in the fourth and f intercostal spaces. Its beat was distinct in the paraste line and one inch outside the mammillary line. The car dullness begins in the sixth interspace out, ½ in. to the of the mammillary line, and passes to the right into l dullness. Over the apex, sixth intercostal space, out the mammillary line, a rough systolic murmur can be h and a distinct diastolic tone. A like murmur, but wea can be heard over the lower third of the sternum. Over base of the heart and pulmonary area the same auscultat phenomena are heard. Over the aorta there is hear continuous murmur.

Nicoladoni, 1876.—This surgeon observed another le of this type in a bricklayer, aged 22. This lesion apparently congenital. Since he was two years of vascular tumours had been noted on the third, fo and fifth fingers, in the palm, and on the dorsum of the hand. The patient complained of pain, weakness, cramps. The skin also became ulcerated. The increas circumference of the hand was about 5 cm., and there wa increase in length of this side of 6 cm. The functio the hand was fairly good, although there was some discon and disability. No operation was performed. Bandages applied.

Israel, 1877.—Girl, aged 9. The right leg is larger tha left. The thighs and feet on both sides are the same Veins prominent in the skin, an ulcer of which had pers for some time. Pulsation noted in the upper two-t

of the leg between the crest of the tibia and the peroneal region. Posteriorly, pulsations were not noted or other changes. Thrill most pronounced at the point where anterior tibial artery pierces the interosseous membrane. This point marks the upper boundary of the pulsating area. A loud bruit is heard here, which in the description corresponds to the machinery-like murmur heard in this type of aneurysm. The right femoral artery is wider than the left. This statement applies also to the external iliac. No thrill is felt when the hand is placed on the femoral artery as it passes over the pubic bone. A thrill is felt, however, over the femoral vein at the level. The pulse wave in the right dorsalis pedis is delayed. In the right posterior tibial the pulse appears at a perceptible interval than in the left, but considerably earlier than in the dorsalis pedis on the same side. The apex-beat of the heart is diffuse and entirely to the left of the mammary line. Both the right and left heart are dilated.

The impression was that the lesion was a vascular, pulsating, malignant growth; perhaps a telangiectatic sarcoma with ulceration of the surface, or a disease of the vessels. The diagnosis of a diffuse dilatation in the region of the anterior tibial was made. This developed from the telangiectases and extended peripherally to the beginning of the veins. The changes in the femoral and iliac vessels, the hypertrophy and dilatation of the heart were the result of the increased resistance to the circulation of the blood. Some measure of this resistance was afforded by the pressure in the femoral and iliac arteries and the changes in the apex-beat.

On March 3rd, 1876, the femoral artery was ligated at the apex of Scarpa's triangle. The artery was thin walled. Directly after ligation pulsation ceased in swelling in the leg, which collapsed. The pulse dropped from 96 to 72. Two hours after ligation it was 64; five hours later 42. The rhythm was regular. That evening the patient complained of pains anteriorly over the right knee. The toes were cold, livid and hyperalgesic. On April 11th, Langenbeck performed an amputation through the lower third of the thigh. The patient gradually recovered from this. It is interesting to note that on August 2nd the tension and width of both femoral arteries were the same, and that the right external iliac artery, which had been tortuous and dilated, resembled quite closely the left. The heart had greatly diminished in size.

An examination of the amputated leg showed that the popliteal artery—likewise the popliteal vein—was dilated. The anterior tibial artery is larger than the posterior tibial. This artery was the size of the femoral artery of a child corresponding in age. It became considerably larger distalward until the ulcer in the leg was reached, when it became narrower and was of normal size at the ankle. Numerous thin-walled, lateral branches, as transparent as silk paper, accompanied by thin-walled, dilated veins, were seen off from the principal artery. A solution of fuchsin passed directly through these arteries into the veins. The examination showed that relatively large veins arose from abnormal blood spaces—blood spaces which had a direct communication with the arteries. The arteries and veins communicated with each other without the intervention of capillaries. The lesion was, therefore, a congenital arteriovenous aneurysm.

VON EISELSBERG, 1899.—Female, aged 26. When 4 years old the right leg was found to be larger than the left. Later cramps occurred in the right lower thigh. When the patient was 12 years old ulcers developed without injury over the malleoli of the right leg. These did not heal. Frequent attacks of severe pain occurred, associated with redness and swelling of the extremity. The great toe became discoloured, blebs developed, and the nail came off. The patient was admitted to the hospital because of increasing pain and aggravation of symptoms. When the operation was performed a ligature was placed upon the femoral artery below the profunda. The artery at that point was dilated, its wall was thin. The saphenous vein was ligated just distal to the opening of the femoral. Severe bleeding occurred from the edges of the wound. The day following the operation severe pain was noted, temperature 102·2° F. Three days after the operation the temperature continued high, severe pains developed in the foot, which became cold, discoloured and gangrenous. Anæsthesia developed in the leg and foot. Four days after ligation amputation was performed through the upper part of the thigh. In the specimen, when dissected, was found a large aneurysmal varix involving the popliteal vein and artery. The communication was small and the artery itself was not dilated. The short saphenous vein was thickened and tortuous. Pulsations had been observed at this point.

There were no cardiac changes in this case. The case is noteworthy in that it was one of the early ones in which a direct communication between the vein and artery without the interposition of a capillary bed was demonstrated.

VON SCHRÖTTER, 1899.—Violin player. All the arteries and veins of the left arm became thickened, dilated and tortuous following a strain in gymnastic exercises. New atypical vessels have formed. These form a prominent pulsating elastic swelling on the hypothenar eminence. Loud bruits are heard, and the patient complains of a heavy, pulsating feeling in the entire extremity. The ulnar artery in its upper third was ligated and 1 cm. of the same resected. The pulsating sensation disappeared, and the swelling in the hypothenar eminence became easily compressible. Schrötter thought that in order to completely cure this that it would be necessary to ligate the radial artery, to destroy the dilated vascular spaces by a galvanopuncture, and excise the large venous trunks. Final result in case not given.

BRAUN, 1901.—The patient, a 43-year old male, had had as long as he can remember, in the course of the radial artery above the wrist-joint on the right side, a small tumour. The veins of the right hand and forearm were more marked than those of the left. He had no particular trouble until year before entrance to the hospital, when the hand began to enlarge and cause him severe pain.

Examination.—The right brachial artery was twice as thick as the left, tortuous, and had marked pulsations. The lower end of the radial artery is tortuous, and on it were four aneurysms varying in size from a hazel-nut to a walnut. The hand was red, hot, and sweating. The cutaneous veins of the hand and forearm are extraordinarily full. If the extremity is elevated the veins empty; when lowered they fill. If the brachial artery is compressed, the veins empty. The muscles are atrophied, and there are changes in the joint surfaces of the fingers which resemble arthritis deformans. The sensitivity of the skin is also reduced.

The aneurysms of the radial artery were extirpated. No abnormal communication between the artery and veins was found. After the operation the pain ceased. The other symptoms gradually increased. This was a congenital lesion, and there is difficulty in differentiating it from a cirsoid aneurysm. Ligation of the brachial artery was considered, but not performed because of the effect it might have on the arm. The patient was able to work, and nothing further was attempted.

BALLIN, 1913.—M.F.H., 30-year old steam fitter, had always enjoyed best of health; never used alcohol to any extent. No history of infection. August 11th, 1911, he tried to stop a sliding steel casting with his right hand, hyperextending the hand at the wrist with great force. He felt a sharp pain, and the next day noted the veins on the dorsum of the injured hand were much swollen. Some of these were excised, the attending physician thinking they were varicose. Swelling of the veins returned immediately, and extended slowly to the little finger and on the palmar side into the hypothenar region. The hand was swollen, perspiring profusely, and causing intolerable pain. In spite of repeated operations upon the vessels no relief was experienced, and on Oct. 12th, 1912, the little finger with its metacarpal bone was removed. Hæmorrhage profuse.

The microscopic report is as follows: The specimen from the little finger is a blood-vessel tumour consisting of a large mass of veins (just like the cayus cavernosum). No malignancy. On account of the progressive nature of the lesion an angiosarcoma was thought of. Later, Nov. 14th, 1912, a dilated arterial sac was ligated, which undoubtedly communicated with some large veins. The dilated part was excised and the communication ligated. On Dec. 23rd, 1912, the cavernous mass had returned in the ring and middle fingers, and on Jan. 13th, 1913, an amputation of the forearm was performed. The pathological report by Dr. Warthen, of Ann Arbor, is as follows: The vessels have greatly dilated lumina and much thickened walls, showing that the vascular changes must be of some chronicity, probably congenital, the condition developing after trauma, as has been observed in a number of cases of this rather rare and interesting condition.

EBSTEIN, 1913.—Patient, 24-year old mechanic. A diagnosis of questionable aneurysm of the subclavian artery had been made. The patient had asthma during the winter, and often suffered with "bronchial catarrh." For a year he had complained of a scratching feeling in the neck. Since he was twelve years of age he had noticed that the clothes which his mother made were too short for his left arm and he had observed that his left forearm was longer than the right. Hands were apparently of the same size.

On physical examination the striking finding was a loud thrill, especially in the left supraclavicular fossa. Distinct palpatory findings not noted over the brachial, axillary, radial or ulnar arteries. A bruit is heard in the region of the left elbow over the brachial artery. A distinct thrill is felt at this point. The veins of the left upper extremity are distinctly enlarged. Particularly striking was the dilatation of the cephalic vein, the median basilic vein, and the subcutaneous veins on the radial side of the forearm. The

interosseous artery when the forearm is grasped seems to pulsate distinctly and strongly.

The patient worked as a mechanic. There was no feeling of weight in the arm. The skin was livid. The heart was not enlarged, and the tones were clear. X ray revealed no changes in the heart shadow, and there were no changes in the subclavian artery. The blood pressure on the affected was higher than on the normal side. No mention is made in this case of the bradycardiac reaction. No operative interference attempted.

Ebstein mentions, in a note to the description of this case, another one. This was a private patient of Strümpell's, aged 14, who had had since birth a lesion of the right forearm, which was 3 cm. longer than the left. No other mention is made of this case, and I am unable to find any other mention of it in the literature. The patient evidently had a congenital arteriovenous aneurysm.

PUSCH, 1914.—Boy, aged 12. The entire right upper extremity was affected. The supraclavicular, axillary brachial, radial, and ulnar arteries are markedly dilated. Two sharply circumscribed dilatations were found upon the radial and ulnar arteries, the size of a pfennig or pea, not far from the wrist-joint. A continuous murmur was heard over these. In the palm of the hand more such circumscribed dilatations were found. Besides these were a number of angiomatous nodules, bluish-red in colour, and compressible on the fingers. The right arm was 5¼ cm. longer than the left and considerably warmer. Two small ulcers were present at the terminal phalanges of the third and fourth fingers. Pusch regarded this case as noteworthy because of the extent of the disease; marked enlargement of the heart because of increased work, and relative aortic insufficiency. Prognosis grave; it being scarcely doubted that the lesion would become worse during the year. Final result not stated.

EBSTEIN, 1918.—Male, aged 49. At the age of 32 the patient had complained of rheumatic pains in the left arm and especially of tingling in the finger-tips. During the past five years an increasing swelling of the veins of the left upper extremity had been noted. After walking some distance the extremity became heavy. The length of the right forearm was 29 cm.; of the left, 31 cm. The left forearm measured when the fingers were extended 45¼ cm.; the right, 42 cm. The circumference of the right arm was 25 cm.; of the left, 28½ cm. The circumference of the right elbow was 26½ cm.; of the left, 29 cm. A distinct thrill could be felt in the left supraclavicular fossa and a loud blowing bruit heard. The entire left upper extremity felt considerably warmer than the right. A distinct difference in radial pulse was noted. Heart tones normal. No enlargement of the heart noted. The final outcome in this case is not recorded.

HALSTED, 1918.—The patient was admitted to the Johns Hopkins Hospital in 1911. When the child was three days old the mother noticed a throbbing swelling in the child's neck. Right-sided headaches, earaches, toothaches lasting two or three days, and frequent epistaxis were complained of. Throbbing in the neck gradually increased. On physical examination a pulsating tumour was found beneath the lobe of the ear on the right side. The ear pulsated synchronously with the heart beat. No dilatation of superficial veins of the face. An aneurysmal sac was found behind the ascending ramus of the jaw. A continuous thrill and bruit were present which disappeared when pressure was made over the venous sac or the carotid artery. The internal jugular vein was dilated. At operation the external jugular vein was found to be enormous. It was excised. An H-shaped plexus of dilated, pulsating veins was found. Beneath this mass of veins considerable proximal dilatation of the common and external carotid arteries was noted. The internal carotid artery was small. One communication existed between the external carotid artery and sinus-like veins which were dissected free and removed. The external carotid artery was ligated proximally. The pulsation and thrill ceased. When the first dressing was made, six days later, the thrill, bruit, and visible pulsation had returned.

The patient was admitted to the Johns Hopkins Hospital again in 1918. The throbbing and swelling of the right side of face had become worse since the operation. The veins of the face were dilated. The patient's face appeared cyanotic and the veins of the face were dilated. A tumour was noted at the angle of the jaw. This, the size of a hen's egg, pulsated, and a continuous thrill and bruit which were transmitted over the face could be heard over it. The pulsation was more forceful than before the operation. Pressure over the tumour caused the thrill and bruit to disappear, and distention of the veins of the face. The heart was normal. The aneurysm now involved the right parotid, new channels had apparently developed. The temporal vein was ligated at this time. Double ligation of a so-called aberrant artery and vein and a large medial vein caused obliteration of the fistula, with disappearance of the thrill and bruit.

Subsequent examination made upon this patient revealed a disturbed vascular mechanism. The lesion was progressive, the entire face eventually showing an angiomatous change. This patient has not been cured. It is undoubtedly a case of congenital arteriovenous fistula, in which multiple fistulæ exist between the external carotid and ascending pharyngeal artery and large anomalous sinus-like veins. The anastomosis was of the end-to-end type. Careful studies of the heart were made but no changes found.

SONNTAG, 1919.—Girl, aged 16. Since birth a bluish discoloration of the ball of the right thumb had been noted, likewise elevation of temperature, abnormal amount of pain, increased secretion of sweat and pigmentation. Increased blood pressure on the right side. The affected extremity was larger than the normal. An ulcer developed upon the volar surface of the thumb, which apparently bled quite profusely. When the patient was 14 years of age a resection of the radial and adjacent arteries with veins was performed. The arteries and veins in the upper third of the forearm communicated with each other. Nine months later, because the lesion had become worse and bleeding from the ulcer, resection of the veins in the forearm and hand was performed. Two years later, because the lesion was still progressive in the ulnar vessels, a resection of the ulnar artery below the elbow was performed, combined with elevation and constriction. When the report was made the lesion was stationary and the ulcer had healed.

RIENHOFF, 1924.—Male, aged 20, admitted to Surgical Service of the Johns Hopkins Hospital, Jan. 7th, 1924. He complained of a pulsating, rumbling mass in left side of neck. When the patient was three weeks' old the parents noticed a pulsating swelling on the left side of the neck immediately below the lobe of the ear. As far back as the patient can remember he had always had this throbbing pulsating tumour; but he thought that it had not increased in size more rapidly than the structures about it, so that relatively it was no larger than at birth. Frequent attacks of epistaxis occurred, which were difficult to control. As a boy, the patient had noticed that he was definitely more short winded than his playmates. This condition was, however, never embarrassing. There were never any symptoms indicating a cardiac lesion. At times the patient experienced attacks of dizziness, especially after severe exercise, excitement, or pressure on the left side of the neck. There was always a roaring and rumbling in the neck which could be easily heard over the head, but which bothered him only at night when lying on the left side. A tight collar caused a large vein on the left side to become larger, and the left side of the face to feel much warmer.

On examination, a pulsating tumour was found on the left side of the neck, below and to one side of the angle of the mandible on the left side. The left ear was displaced laterally with each pulse beat. The arterial pulsation on the left side was approximately twice as wide in excursion as on the right side. On palpation, a buzzing thrill and machinery-like hum could be felt over the left side of the neck and head. The maximum intensity was over an area just below the angle of the jaw, where there was a forceful expansive pulsation. The thrill was transmitted into the superficial veins, both distally and proximally, the veins seeming to have an arterial pulsation.

When pressure was made at the base of the neck on the left side, just above the middle of the clavicle, a large vein measuring about 3 cm. in diameter filled from above downward. This pulsated vigorously. The common carotid artery could be palpated throughout its length. It seemed to be almost three times as large as the one on the right side. The common carotid artery did not seem increased in length. It was not tortuous. The temporal artery on the left side was smaller than on the right. There was no suggestion of a collapsing pulse. Occlusion of the left common carotid artery caused cessation of pulsation in the aneurysmal tumour and disappearance of the thrill. Complete occlusion of the left common carotid artery was associated with a feeling of dizziness and diplopia. The pulse decreased from 20 to 30 beats per minute, while the systolic and diastolic blood pressure increased 20 mm. On auscultation a marked rumbling, to-and-fro, machinery-like murmur was heard over the entire left side of the head and neck, the maximum intensity being over the point of greatest pulsation in the tumour.

Examination of the eye grounds revealed very interesting changes. The left retina was more vascular than the right, having a lighter shade of red. The margin of the disc was not as sharp on the left side as on the right. The retinal veins on the left side were much larger, more tortuous, a lighter shade of red, and pulsated more vigorously. Occlusion of the left common carotid or pressure at the point of communication caused a cessation of pulsation in the retinal veins and a marked decrease in size. Pressure on the large vein at the left side, probably the external jugular, caused a marked engorgement of the left retinal veins.

The pulsation extended into the mouth, causing the left tonsil to move upward and toward the median line.

When the external and internal carotid arteries were exposed some interesting changes were found. (Fig. 14.) The internal carotid was very small, and the external carotid artery was much dilated up to the point where it crossed under the large vein. The external carotid artery passed upward and towards the midline, making a turn about the digastric muscle and then running lateralward under the large external jugular vein, where the artery again turned for the second time and passed under the mandible on the left side in the general course of the external maxillary artery. As the artery passed under the mandible it became smaller, rapidly approximating in size a normal artery. No internal jugular vein was found.

Eight fistulous communications were dissected out between the external carotid artery and the anomalous external jugular vein. Three of the fistulæ were situated on the posterior aspect of the vein, and five on the anterior. The uppermost fistula trifurcated just before entering the vein. The upper anterior fistula was closed by a lateral suture of the arterial wall. Complete cessation of the thrill and pulsation did not occur until the last communication had been divided. The artery and vein were completely separated, the lumina being patent when the operation was completed. The patient was completely relieved by this operation.

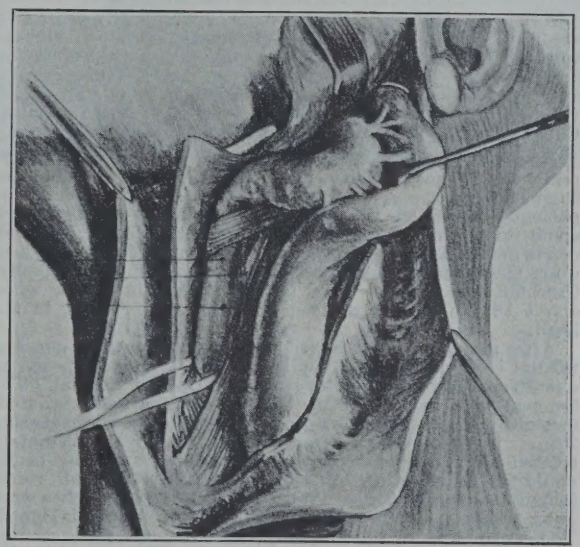
REID, 1925.—Male, aged 18. Five years before admission to the Johns Hopkins Hospital a puffing noise was noted in the region of the right shoulder and neck. Six months later, after severe exercise, a soft pulsating mass about the size of the end of the little finger was noted in the right supraclavicular fossa. This increased steadily in size. When examined, a large mass was found which involved the right side of the neck and the supraclavicular region. Dilated vessels in and beneath the skin gave the appearance of earthworms. Marked pulsation was noted in the larger veins. A continuous bruit and thrill were heard over the mass. The external jugular vein was greatly dilated. Electrocardiogram and teleorentgenogram were normal.

On Feb. 25th, 1929, the anterior half of a large mass of veins forming part of the aneurysm was excised, and a large artery, probably the transversus colli which communicated directly with one of the distended veins, was divided. On May 28th, 1920, the internal and external jugular veins were excised, and the subclavian vein ligated proximally and distally to a wide communication between the subclavian vein and the aneurysmal veins. The fistulous communication between the subclavian artery and the sinus-like veins was ligated. The subclavian artery was also ligated distally and proximally to the thyroid axis. The fistulous communications were about the size of the little finger, and seemed to run end-to-end into venous trunks. The veins posteriorly forming a part of the lesion were not excised. There was no pulsation or bruit following the operation. The patient was cured.

This case undoubtedly represented a congenital arteriovenous fistula, with multiple fistulous communications, end-to-end, between the subclavian artery and transversus colli arteries and the venous sinuses. No cardiac changes were noted in this case, although the lesion had lasted at least five years, probably much longer. The fistulous communications between the arteries and veins were quite large. They did not seem to function, judging from the history until the patient was about 13 years of age, when, suddenly, channels which had remained latent opened without any apparent cause. From the time that the openings developed there occurred a rapid and progressive growth of the tumour, as in the Halsted case. In both of these the anastomosis was end-to-end. There was no evidence of new growth in the sections, and the direction of the blood flow and intravascular pressures were directly and primarily responsible for the enlargement and apparent growth of the vessels.

REID, 1925.—Female, aged 35. When five years old the patient fell, striking the right knee. An unusually large hæmatoma developed. It was noticed then that the right leg was larger and longer than the left. The veins were slightly dilated. Until the patient was 22 years of age there were cramps had been noticed in the leg and a marked dilatation of veins. The leg was bluish in colour and the patient wore a bandage for support. Following an attack of diphtheria, the patient remained in bed eight weeks because of pain in the leg. When 30 years old the patient noticed throbbing and pulsation in the veins of the leg. He remained in bed six months. Cocaine was required to relieve pain. An operation for varicose veins was performed elsewhere. Some dilated superficial veins were removed. Hæmorrhage—difficult to control—was brisk. The circulation in the leg was much impaired after the operation. The right leg was found upon examination to be 6·5 cm. larger than the left. Blood pressure in the right leg 160/25; in left leg 140/65. A systolic thrill and continuous bruit can be felt and heard over the right femoral and iliac arteries. Venous engorgement of the right leg from the knee to the dorsum of the foot is noted. The right leg is larger than the left. The popliteal artery on the right side is greatly dilated and tortuous. A continuous thrill and bruit can be felt and heard over it, most marked on the outer side anterior to the upper end of the fibula. The posterior tibial and dorsalis pedis on the right side are smaller than on the left. The bruit could be heard over the entire leg, but would disappear when the anterior tibial artery was occluded by pressure. When the leg was elevated and the veins

FIG. 14.



Reproduction of figure from Rienhoff's article, showing the lateral communications between arteries and veins. Cure followed division and ligation of these communicating vessels. In the second case, reported in this paper, the ligation of the communicating vessel could be made, and the signs and symptoms of an aneurysm disappeared.

collapsed the tibia felt rough (moth eaten). Roentgenogram measurements indicated that the right femur was 1·5 cm. longer than the left; the right tibia 5·5 cm. longer than the left, and the right fibula 4·5 cm. longer than the left. The right tibia was apparently perforated by large canals through which vessels ran. The nutrient artery was larger than normal. No cardiac change; the teleoroentgenogram and electrocardiogram were normal; the Wassermann reaction negative.

Operative Procedures.—The popliteal vein was enormously dilated and filled with arterial blood. The anterior tibial artery was ligated and divided at the interosseous membrane; it was very thin and dilated. The popliteal vein was ligated and divided above and below the junction with the anterior tibial veins and then excised upward. All the geniculate branches of the popliteal artery were ligated. The bruit was reduced in intensity by ligation of the anterior tibial artery. The popliteal artery was thin and much dilated. Ligation of the lower lateral geniculate artery caused cessation of the thrill. Two days after the operation the bruit returned; 85 hours after the operation a hæmorrhage, followed by gangrene, occurred, and an amputation was performed above the knee. The anterior tibial artery had ruptured proximal to the ligature; the ligature had not slipped. An examination revealed that five branches of the anterior tibial artery ran into the tibia, communicating with a sort of reservoir which was drained by five tributaries to the veins accompanying the artery.

ERDHEIM, 1926.—R. S., aged 32. In 1917, a sack of potatoes, weighing 80 kg., fell upon the right shoulder. About three weeks later the patient noticed under the right clavicle a dilatation of the vessels, and within a short time a dilatation of the vessels of the right arm was noted. Nine months after the accident distension and tenseness of the abdomen appeared. During childhood the vessels were more marked in the right forearm than in the left, and the extremity was thicker and longer. In the hypothenar eminence of the hand was a bluish compressible mass, projecting 1 cm. above the level, which had the characteristics

of a hæmangioma. Compressible, no thrills, no pulsation. The skin over the veins was thinned. It appeared as if the veins would rupture. The mass is painful. The subcutaneous veins in the thenar eminence are dilated and tortuous. The subcutaneous veins on the volar surface of the forearm are tortuous, the size of a lead pencil. They empty into a vein at the bend of the elbow, the size of the thumb. The vein corresponding to the basilic is tortuous and greatly dilated. These are easily compressible and move beneath the skin. The radial, ulnar and brachial arteries feel wider than normal, and pulsate stronger than normal. The hand, especially about the hypothenar eminence, feels warmer than the left. This patient suffered from nose bleeding, hæmorrhage from the skin, and late in the course there developed a thrill and bruit synchronous with the pulse, which could be heard in the lower third of the arm.

Autopsy Findings.—Cirrhosis of liver with beginning atrophy. Perihepatitis and perisplenitis, chronic; chronic splenic tumour. Varices of the œsophagus, with perforation and ascites. Phlebectasiæ parietis dextri thoracis and extremitatis superioris dextræ; angioma et telangiectasiæ volarmanus dextræ. Parotitis pawlenta acuta dextra. Congenital tumour made worse by an injury at 26.

PERTHES, 1927.—Woman, aged 27. When 3 years of age and wearing the first shoes, the left foot was larger and longer than the right, and the entire leg was swollen. Since the patient was 10 she has had cramps in the leg and dark spots on the outer and inner sides of the foot. Bleeding ulcers made the patient go to bed. Five operations performed upon the vessels without result. The wound healed badly. Gradually increasing pain in the knee-joint, and when about 18 the patient noticed pounding and roaring in the head.

After many days' rest in bed the bruit was localised over the medial condyle and the popliteal fossa. When exposed at operation the femoral artery appeared about normal. The femoral vein, on the other hand, was markedly dilated, measuring from 2 to 2½ cm. A thin-walled vein measuring 2 mm. in diameter was found upon the artery intimately related to it. When compression was released the bruits could be heard; those in the adventitia, the small veins, felt like a vibrating wire. When small lateral branches were cut it was seen that they were filled with bright arterial blood. Ten centimetres of the femoral, whose exposed walls seemed to be thinned in places, were resected. The wound healed well, circulation good, but, seven days after resection, bruits and thrill heard and felt over the medial condyle, which became more intense and extensive. Pain in foot and paræsthesia reappeared, and patient again complained of pounding heart and roaring in the head. Veins as prominent and full as before the operation. In view of the arthritis the thigh was amputated at junction of middle and lower third. The relation between the vessels in the popliteal fossa was like those in a traumatic arteriovenous fistula, with the exception that in the traumatic there is one communication; while in this there were many, and it seemed as if the arterial blood passed through a wide meshed sieve into the veins. This abnormal communication occurred in a congenital angioma. Whether the tissue found in the popliteal fossa was a growing angioma is not decided.

RÖSLER, 1928.—Boy, aged 15, always healthy, no injury. When 7 years old definite changes were noticed in the right hand. The right upper extremity is larger than the left. There is a soft part and swelling on the thenar eminence of the right hand and the base of the second finger. The swelling is elastic. Venous markings prominent about the swelling. Veins in the cubital fossa dilated. In the region of the brachial and radial arteries marked pulsations palpable and thrills. At the end of the radius on the volar side a pulsating mass of vessels is found. The veins on the dorsum of the hand have visible and palpable pulsations. A systolic and diastolic bruit are heard over the vessels. Temperature of forearm and hand elevated. Hand darker than left. When the extremity is elevated skin becomes paler. Skin bluish-violet in colour. Blood pressure: right, 120/70; left, 105/70. Cardiac: apex-beat fifth intercostal space in the midclavicular line, heaving and diffuse. Cardiac dullness extends on right, one and a half finger-breadths of the sternal margin, to the left and above, no widening. At the apex loud 1 and 2 tones; over the base pure tones. Second pulmonic somewhat louder. Lying, 82. Sitting, 84. Standing, 100 rhythmic. Compression of the right forearm or arm: no changes in frequency of beat, and only slight lowering of blood pressure. Electrocardiogram: no variation from normal. Rontgen: heart was spherical, moderate enlargement of both sides. Transverse, 13·7 cm.; thorax, 23 cm.; pulsation within normal. Compression of right forearm or arm gives no changes in size of heart or excursion. Outcome not recorded.

PEMBERTON AND SAINT, 1928.—A man, aged 30, visited the Mayo Clinic in 1925 because of a progressive abnormality of the right upper extremity. This had always been larger than the left. When 13 years old he injured the little fing on the right side while playing baseball. Ankylosis gradual developed. Even a slight abrasion of the finger requir from one to two months to heal. In 1918 he began to noti that the veins on the back of his hand were becoming mo prominent, and that there was a tendency to numbness the affected arm and hand.

He first visited the clinic in 1922, when a typical arter venous thrill was felt at the base of the thenar and hypothen eminences. A bruit with systolic accentuation could heard over the thrill. Atrophy and gangrene of the dist phalanx of the little finger were noted. An arterioveno aneurysm of the right ulnar artery and vein, just distal to t annular ligament, was excised, and the artery proximal to t aneurysm was enormously dilated, the diameter bei about 25 cm. The radial artery was exposed and found communicate with a large vein in the anatomical snuff-bo The ankylosed little finger was amputated at this tim In 1923 ulceration of the index-finger occurred. There w no history of trauma. Gangrene occurred. The patie returned and the finger was amputated. The patient becar gradually worse and the right hand became a hindran In 1925 dry, atrophic ulceration appeared at the site of t amputated index-finger and on the middle finger. The hea was markedly enlarged, and a marked systolic thrust w seen over the lower part of the præcordium. There was systolic murmur over the base. No signs or symptoms cardiac decompensation were present. The venous blo in the neighbourhood of the arteriovenous communicati contained so much oxygen as to be almost arterial.

Amputation was performed through the forearm. D section of the specimen disclosed dilatation of both arteri and veins, and multiple fistulæ between them. It is of intere to note in this case that while the solution fills the dilat proximal arteries and veins, the more distal vessels are on partially filled because of the short circuiting, due to t fistulous communications.

PEMBERTON AND SAINT, 1928.—A man, aged 24, enter the Mayo Clinic in 1922. The right foot had been larg than the left as long as he could remember. In 1909 ingrowing great toe-nail was operated upon. Infecti occurred and pus was discharged for four years, the t eventually turning black. In 1913 there was a sudd hæmorrhage from the dorsum of the right foot near t metacarpophalangeal joint; the bleeding was stopped binding the foot. The great toe was amputated in 191 and since that time there have been several hæmorrhage The patient had noticed that the right foot was much swolle and he felt pulsations in the foot, leg and thigh. An ulcer tion on the dorsum of the right foot persisted. A ye before the patient's admission to the clinic an operati was performed. It is probable that the anterior and posteri tibial vessels were ligated. All the superficial veins of t right leg were greatly dilated. Thrills and bruits we present from Poupart's ligament distally as far as the toe The right foot felt like a mass of spongy tissue. Pressu over the internal saphenous vein immediately caused t foot to swell. There was a loud blowing, systolic, apic murmur, and the lesion of the heart was diagnosed chron mitral endocarditis, with regurgitation (as the patient ga a history of previous rheumatic fever, the condition of t heart could not be attributed unequivocally to the lesi in the lower extremity).

At the first operation, May 4th, 1922, the anterior tibi artery and the veins on the dorsum of the foot were ligate The artery just proximal to the transverse crural ligamen was dilated to a diameter of about 3·7 cm. The wall w markedly thinned. The arteriovenous communication cou not be definitely located. At the time of the second operatio July 20th, the bruit and thrill still extended above th popliteal space; the leg was amputated in an attempt t preserve a useful stump. All veins were markedly enlarge some to a diameter of 3·75 cm.

The patient was examined August 16th and the conditio found to be satisfactory. The veins were not enlarge as before the operations, and no thrill could be felt or bru heard.

PEMBERTON AND SAINT, 1928.—A girl, aged 16, w admitted to the Mayo Clinic for a lesion of the left foot. H mother stated that from the time the patient was a baby t left foot had not seemed quite normal, and when the chi reached the age of 8 years this foot seemed to be hott than the other. Three years later small scabs began appear on the dorsum of the toes, gradually increasi in size and accompanied by a discharge of greenish pu Because of the spread of the ulcerous area, the out four toes were amputated in March, 1924. The girl w told at this time that she was suffering from tuberculosis the foot. The great toe was amputated in November.

Posterior to the internal malleolus was an area abo 3 cm. in diameter over which a distinct thrill synchronous wi the pulse was palpable. On the dorsum of the foot a simil

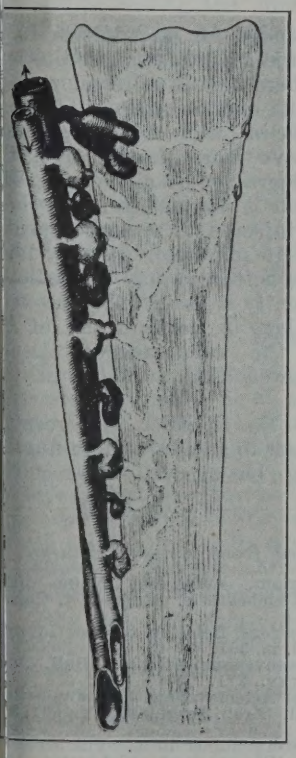
thrill could be felt over a larger area. On auscultation a loud, continuous bruit, with exacerbations corresponding to the systole, could be heard. This bruit, although of maximum intensity over the areas mentioned, could be heard as far proximally as the middle of the calf. The legs were equal in length. The heart was not enlarged. The first initial sound was accentuated. Calorimetric studies were made with the Stewart Hegeries foot colorimeter, and the left foot was emitting nearly 12 times as much heat as the right. The venous blood from the left foot contained more than four times as much oxygen as that from the right, and consisted of nearly pure arterial blood.

On June 26th the dorsalis pedis and posterior tibial arteries of the foot were ligated. As a consequence the foot seemed to improve for a short time. After a few weeks the foot began to cause pain again, and the scab-covered sinus at the distal end of the foot did not show any signs of healing. The foot was amputated. Pathologically this seemed to be a case of multiple varicose or cirsoid aneurysms.

PEMBERTON AND SAINT, 1928.—Man, aged 20 years. At birth the right arm was larger than its fellow. Symptoms were not noted until he was 11 years of age, when he began to have spells during which the arm became swollen and painful with accompanying malaise. After the second spell, the wrist and fingers became ankylosed and suppuration of the middle finger occurred. When examined, an arteriovenous bruit was heard in the palm and also in the clavicular region of the right side.

At operation the radial and ulnar arteries were ligated and divided, and all the vessels in the neighbourhood of the wrist-joint were enlarged. The hand was reduced one-third in size, and the bruit and pulsation were considerably reduced following the operation. The patient was seen again in 1920. Six months previously he had noticed a dark scab over the first joint of the little finger. A month previous to this visit the scab gave place to progressive ulceration. Amputation through the middle of the forearm was performed.

FIG. 15.



This diagrammatic drawing is from the case reported by Reid. Amputation made necessary by gangrene which followed operation. The multiple communications which exist between artery and vein, extending even into the bone, render cure of such a lesion practically impossible.

The patient returned in 1924 because of swelling in the region of the right clavicle. There was swelling in the supra- and infra-clavicular fossa on the right side. The stump of the right forearm was about three times the normal size, but tapered off toward the shoulder. A systolic pulsation was visible in both clavicular areas, and a systolic thrill most pronounced was felt in the supraclavicular space. The whole arm pulsated with each systole. A loud, continuous bruit, with systolic accentuation, could be heard through the right arm and clavicular region, most marked in the supraclavicular space. The superficial veins of the right arm were dilated to three or four times their normal size. The heart was markedly enlarged, the apex-beat being visible in the sixth intercostal space. Blood from the veins on examination was almost arterial in character as determined by the oxygen saturation method. No further operative interference attempted. Patient cannot be traced. Several attempts have been made. No mention made of bradycardiac reaction.

Summary.

The 30 cases which have been studied in this paper, 24 in the literature and six of my own, indicate the difficulties which may be encountered in the treatment of lesions of this type. The operative treatment is more difficult than that of traumatic arteriovenous aneurysms because the communications are usually multiple, and frequently so situated, when the aneurysm occurs in the extremity, that they cannot be reached. How difficult obliteration of some of these communications may be is indicated by one of Reid's cases (Fig. 15), in which there were multiple communications between the arteries and veins. The communications in the bone itself were almost sinusoidal in character. In Case 1, reported by me, the X ray picture indicates the difficulties, for the radius contains many large foramina through which undoubtedly the arteries and veins communicate directly.

In six of the cases in which the aneurysm occurred in the upper extremity (Letenneur, Krause, Obalinski, Ballin, Pemberton (2)), amputations had to be performed either because of repeated hæmorrhages which could not be controlled, or what has seemed to the surgeon having charge of the case as the malignant nature of the lesion. Malignant in the sense that the vessels enlarged rapidly and destroyed tissue. These lesions, however, show in no instance any relation to malignant hæmangiomas or other tumours which form metastases.

In seven cases (Gross, Israel, Eiselsberg, Reid, Perthes, Pemberton (2)) amputation through the lower extremity has been necessary. In some of these the amputation was necessitated by gangrene which followed ligation of the principal artery. It is interesting that gangrene has followed ligation of the femoral artery, even at the site of election. The dangers associated with ligation of the vessels of the lower extremity in this type of lesion seem to be much greater than after ligation for other causes. Gangrene has supervened and amputation has been performed some time after the ligation.

In three cases has operation been followed by a complete cure. In Rienhoff's case the multiple lateral communications between the artery and vein could be exposed and each one closed; in Reid's case the vessels communicating with each other could be excised, and in Case 2, mentioned by Lewis in this paper, the small communicating vessel could be ligated. In this last case the signs and symptoms associated with the aneurysm disappeared after the

FIG. 16.

Ulceration of the skin occurred over many of the large sinuses in which thrombosis occurred after operation in which the brachial artery was ligated, and the large vein in which the machinery-like thrill was heard, removed. The thrombosis occurred even in many of the vessels of the small muscles in the palm of the hand. Some mummification of the end of the thumb occurred almost six weeks after the operation.

operation, but a mass of veins still persists in the skin over the lower third of the humerus posteriorly.

I have recently had an opportunity to examine the patient referred to under Case 1. Fig. 16 is a photograph recently taken. In this many ulcerating areas covered by crusts are found in the skin. These ulcerations occurred over dilated vessels in which thrombosis was occurring. Thrombi developed in the vessels of the small muscles of the hand, and contracture of the fingers is due, I believe, to the organisation of the thrombi. This patient has improved decidedly since the operation, but a thrill can still be felt and a bruit heard over the outer side of the lower third of the arm. The bradycardiac reaction can no longer be elicited. Enough facts have been cited to show the difficulties that may be encountered in the treatment of congenital arteriovenous aneurysms. Of the 27 cases in which the aneurysm occurred in the extremities, amputation has been performed in 13, about 48 per cent. Multiple operations may be required. I believe that the large veins in which the thrill is greatest and the bruit loudest should be attacked first, when possible, after the artery has been closed temporarily by a rubber-shod clamp. Ligation of the arteries in the extremities has been followed by a high percentage of gangrene, and even in Case 1, reported in this paper, some mummification of the thumb followed ligation of the brachial artery or the circulatory changes subsequent to it.

The bradycardiac reaction will disappear when a great amount of blood is no longer shunted directly into the veins from the arteries. A heart which has been dilated and decompensated as the result of the disturbed vascular mechanism will return to normal when the fistulous communications are closed or removed by amputation. The return to practically normal of a badly damaged heart is illustrated by Israel's case, in which an amputation was performed above the level of the aneurysmal communications.

Congenital aneurysms do not differ from the traumatic relative to the bradycardiac reaction and the cardiac changes. Whether or not these are present depends upon the amount of blood shunted directly from the arteries into the veins, no capillary bed intervening.

ON EXCRETION UROGRAPHY.

By ROBERT V. COOKE, M.B., CH.M. BRISTOL, F.R.C.S. ENG.,

ASSISTANT IN THE SURGICAL UNIT, WELSH NATIONAL SCHOOL OF MEDICINE, CARDIFF.

EXCRETION urography is now fairly generally practised, and it must prove a most valuable aid in the diagnosis of urinary tract lesions. Since April the method has been used on some 36 cases in the Surgical Unit at Cardiff, and a brief account of the experience gained may prove helpful. Most of the cases dealt with were out-patients. It was hoped that more complete and precise diagnoses would in this way be possible without recourse to instrumentation of out-patients, and so something would have been done to lessen the pressure on hospital beds.

Previous papers have outlined the interesting history of the subject; while there is no question of the new method displacing the old, it is not to be wondered at that since the introduction of cholecystography attempts have been made to find some opaque substance which would be excreted by the kidneys in sufficient concentration to provide readable pyelograms, ureterograms, and cystograms.

Method of Administration.

I have not thought it necessary to eliminate the possibility of iodine idiosyncrasy before the injections. The iodine in uroselectan is in a stable form of organic combination, and as such passes through the body unchanged. Iodism had not been observed in any of the cases.

The quantity recommended for an adult is 40 g. This means having to inject 100 c.cm. of solution. If 60 g. are used then there is still more solution to inject. It is by no means easy in some patients to find a vein suitable for the injection of so much fluid, and two cases really gave more trouble than the ordinary retrograde pyelography usually does. The recently prepared solution is warmed to body heat and may be quite safely injected all at once provided it is injected slowly (10–15 minutes). A very large syringe is useful. It is better to use a needle as large as can be conveniently inserted into the vein. Every care must be taken to prevent any of the solution leaking into the subcutaneous tissues. Painful induration followed this accident in two cases.

Dosage and toxicity.—No ill-effect has resulted from giving 60 g. of the salt to an adult. In a number of cases I have given 60 g., but generally the resulting

pyelograms were little, if any, better than when 40 g. were given. A kidney which is functioning poorly gives a very indistinct shadow in spite of the increased uroselectan injected. At the time of the injection there may be transient thirst and a sensation of tingling and warmth of the skin. No serious symptoms have been observed. In one case of polycystic disease in which the blood-urea was 160 mg. per 100 c.cm. a dose of 60 g. produced no untoward effect whatever. It also produced no shadow. The kidney function must be very bad before the test becomes dangerous.

Preliminary preparation of patient.—The value of clearing the large bowel of gas cannot be too much stressed. These pyelograms are at best often faint, but yet perfectly capable of accurate reading provided they are not fouled by large bubbles of gas. Several results were ruined through neglecting this small matter. A good purgative is given at 2 P.M. on the day preceding the test. Enemata are not recommended.

Radiography must be of the very best. Shadows are too often too faint to be useful; but, on the other hand, with careful technique, a shadow capable of accurate interpretation may be forthcoming. Many of these pyelograms are quite good enough for diagnostic purposes. Relatively few of them allow of good production in print. The best shadows are never so intense as those obtainable with iodide solutions. The Americans use a Hickey bag to secure temporary compression over the bladder region. S. Lubash claims to secure much better visualisation in this way—at the expense of very little discomfort to the patient. Towards the same end the same writer lays stress on the value of withholding urination during the procedure.

Time to take the pyelograms.—It is recommended that pictures are to be taken at intervals of a quarter of an hour, three-quarters of an hour, and one and a quarter hours after the injection. The time at which the best pictures are possible may be fairly constant in the case of the normal kidney. In cases where functional activity is impaired the most intense shadows appear at very varying intervals. It is often necessary to continue the taking of plates at intervals for several hours before visualisation is possible. If this is so, the test becomes both tedious and expensive.

Results.

Since the excretion-rate of uroselectan is a measure of renal efficiency (or at any rate a measure of renal activity at the time), it is at once obvious that the method has its limitations. The absence of a shadow may indicate a derelict kidney (or even an absent kidney), but one may be left at a loss to know what process underlies the renal derangement. In many such cases a precise diagnosis was only possible when cystoscopy, ureteric catheterisation, and retrograde pyelography had been carried out.

Two cases of *polycystic disease* gave no shadow allowing of interpretation. The older method produced typical pictures at once. In one such case there was threatened uræmia with drowsiness, thirst, and a blood-urea figure of 160 mg. per 100 c.cm. No shadow resulted even with 60 g. of uroselectan. Also no untoward symptoms resulted from the injection, showing how free from toxicity the substance is.

Cases of *urinary tuberculosis* are usually investigated without recourse to pyelography. Good pyelograms, however, may be of great assistance in the diagnosis, and in three children with suspicious symptomatology perfectly clear visualisation of normal calices were obtained with 20 g. uroselectan. In this way valuable assistance in diagnosis was obtained without instrumentation. These shadows, though quite readable, were too faint to reproduce in print.

Abdominal swellings of uncertain nature: renal anomalies.—The kidney is all too frequently forgotten in the diagnosis of both the acute and the ordinary abdominal case. There is no need to emphasise the value of pyelography in the diagnosis of an obscure abdominal or pelvic swelling. Without instrumentation and with little disturbance to the patient an injection of uroselectan may clear up a difficult problem of diagnosis. Two such cases have been met with recently.

One presented a tender mass in the right iliac fossa extending downwards into the pelvis. The history was one of sudden acute generalised abdominal pain with vomiting, which had begun three days prior to admission. The temperature was raised and the pulse-rate rapid. Examination revealed a tender mass low down in the right iliac fossa. The clinical picture was very like that of an appendix abscess, but the surgeon was struck by the mobility of the tumour. An injection of uroselectan showed that the swelling was a peculiarly shaped ectopic kidney which had, of course, become infected.

The second case was that of a young women who complained of bouts of nausea, and who, on examination, presented a swelling crossing the mid-line just above the umbilicus. A provisional diagnosis of an anomalous kidney was made. Retrograde pyelography demonstrated a horseshoe kidney. With the advent of uroselectan, intravenous pyelography was carried out some time later. Besides the typical appearances of the pelves and calices the shadow of the whole organ was very clearly seen. The shadow was quite intense, and since the junctional band between the lower poles cast a shadow of equal intensity it was presumed that the kidneys were actually fused and not merely joined by a band of fibrous tissue as they often are.

Renal injuries.—A case was admitted with a history of loin injury and presenting a large tender mass in the region of the kidney. There was profuse hæmaturia. As is usual, an expectant attitude was adopted. After a few days uroselectan was given, and very good pyelograms showed that what damage there was did not involve the pelvis or the calices.

Renal calculi.—The treatment of many cases of renal calculus has been facilitated by this procedure. Patients with calculi presenting themselves in the out-patient department are sent up to the radiological department for intravenous pyelography. In many cases all the preoperative desiderata are obtained at once, since the pictures will demonstrate the presence and function of the supposedly sound kidney and the precise disposition of the stone or stones in the affected organ, and give a very good idea of its derangement and function. Such cases were taken into hospital and operative treatment meted out without delay and without instrumentation, to the saving of our hospital beds.

Hydronephrosis.—Out of eight cases of well-advanced hydronephrosis examined, only two failed to give a good shadow within a reasonable period after the injection. In spite of much enlargement of the pelvis and calices in the other six there was a surprising amount of active renal tissue left—too much to justify nephrectomy. There is much to be said in favour of the conservative treatment of hydronephrosis. Probably many useful kidneys are removed. If possible, the cause of the condition should be dealt with and the organ conserved. In point of fact, in this series of cases all but one had resulted from presence of calculi, which, of course, are always likely to recur in the same or in the other kidney, and the case for conservatism is thus very strong. Where destruction of the kidney had advanced

until little is left save a thin-walled sac, then only a very faint shadow (or even no shadow) is obtained. In such cases, if nephrectomy be deemed advisable, there is no question of removing an organ of value from the patient. The subsequent course and functional recovery of cases of hydronephrosis (and of pyonephrosis) has been followed by injections of uroselectan at intervals after conservative treatment.

Pyonephrosis.—In these cases it is unnecessary to stress the value of a method which allows of a demonstration of the presence and function of the "good kidney" without having to pass a catheter from a bladder containing pus.

Ureterograms.—Only very faint indications of the ureters are usually secured by the intravenous method, unless there happens to be some block in the ureter or unless temporary pressure is artificially secured by means of a Hickey bag or other device. One of the cases of largest hydronephrosis was due to a calculus impacted in the ureter two inches from the bladder. In this case there was a large hydroureter clearly indicated on the radiogram. Even in this case a good shadow was rapidly produced indicating the presence of much active renal tissue, and the treatment contemplated is simple removal of the stone. Uroselectan is most useful, of course, in this type of case. Retrograde pyelography may be impossible owing to the obstruction in the ureter. Uroselectan gives in a simple way a valuable picture of the condition present.

The *cystograms* obtained are good and are secured without the irritation sometimes observed with iodide solutions. The bladder soon collects enough uroselectan in solution to obscure the lower end of the ureter. This fact must be borne in mind when the examination is directed to this region.

Conclusions.

Where a cystoscope cannot be passed, or where ureteric catheterisation (or any instrumentation) is undesirable, difficult, or impossible, we have at our disposal an alternative method of visualising the renal pelvis and calices. In the presence of ureteric obstruction a clear ureterogram may be secured. The method may be of value in the investigation of the urological case in the child; in cases of severe cystitis—tuberculous or otherwise—where catheterisation is very difficult; in cases of profuse hæmaturia; in cases of urethral stricture and enlarged prostate; and in the subsequent examination of a kidney, the ureters of which have been transplanted.

The shadow cast by the excreting renal substance itself is enhanced during the excretory process, so that the size and shape of the kidney substance is often very clearly seen. The excretion-rate and the intensity of the pyelograms give a graphic representation of the function of each kidney at the time. This fact in itself may be valuable in dealing with certain cases such as hydronephrosis with blocked ureters. The excretion-rate, which represents the total renal efficiency at the time, may be ascertained by measuring the output in the urine, or more simply, by following the alterations in the specific gravity of the urine. This has not been found of much practical value. It is important in interpreting the results from the standpoint of function to bear in mind that the functional activity of a kidney can be *temporarily* inhibited, and the non-visualisation at a particular examination does not necessarily mean a permanently damaged kidney.

The method has its limitations, since the shadows depend on renal function, and therefore no shadow, or an undecipherable one, may be obtained in pathological renal conditions. To make a precise diagnosis, recourse to the older method may be necessary, and since in so many cases cystoscopy is absolutely essential it is still quicker (and cheaper) to proceed to ureteric catheterisation and retrograde pyelography in the average case.

Excretion urography is as yet somewhat expensive and uncertain. There must always needs be a percentage of failures, but undoubtedly a most valuable accessory investigatory method has been placed in the hands of the profession.

I am indebted to my chief, Prof. A. W. Sheen, for facilities to carry out these tests. I would thank Mr. Cornelius Griffiths and Mr. J. W. Geary Grant for allowing me to use some of their cases.

"DUKE OF YORK HOME," BRADFORD.—On Thursday last week Princess Mary opened the first block of the new Bradford Infirmary, which is named after the Duke of York. The cost has been about £70,000, but the complete scheme of six blocks is estimated to cost £550,000, of which over £400,000 has been obtained. The present block is intended for paying patients, who will pay 4 guineas a week, and consists mainly of single-bedded rooms. At the opening ceremony Mr. George Priestman, the chairman of the hospital board, claimed that this is the first paying unit to be connected with a voluntary hospital outside London. The building has been erected with elaborate provisions for deadening sound and is warmed from concealed panels in the ceilings.

A BIRMINGHAM HOME FOR MENTAL DEFECTIVES.—On Tuesday last week Coleshill Hall, Warwickshire, which has been acquired by the Corporation of Birmingham, was formally opened as a home for mental defectives over the age of 16. The house and park of 180 acres, which were formerly the property of the Wingfield-Digby family, have been converted to their new purpose at a cost of about £89,000. Four "villas," each of which will hold 60 patients, have been erected in the park and, with the house itself, the colony will accommodate 300 cases—180 women and 120 men—but the arrangements will permit of the ultimate reception of 1000 patients. The large stables have been converted into a steam laundry and workshops have been erected in which carpentry, shoemaking, brushmaking, and other trades will be taught. At the opening ceremony the Lord Mayor of Birmingham expressed the hope that legislative action will eventually make it impossible for the mentally afflicted to have children.

CLINICAL AND LABORATORY NOTES

A CASE ILLUSTRATING THE VALUE OF AVERTIN IN UNUSUAL CIRCUMSTANCES.

By J. Blomfield, M.D. Camb., O.B.E.,
SENIOR ANÆSTHETIST TO ST. GEORGE'S HOSPITAL.

Circumstances do not often arise in which it is advisable to operate on a patient against his will and without his knowledge. It is perhaps worth while, therefore, to record a case in which these conditions were present and were met with so much success that the patient never knew that any operation had been performed on him, much less that his abdomen was opened and that a condition was dealt with which, unoperated on, must have led to death within a short period of time.

A man, aged 50, suffered from anomalous abdominal symptoms for weeks, but eventually showing signs of acute trouble underwent a laparotomy. A gangrenous appendix was removed. A week later there was a septic pulmonary embolus, followed by an abscess in the lung and expectoration of pus. The patient was by now very gravely ill and much reduced in weight, but the pulse remained strong and of good quality, and it was reasonable to hope that the lung trouble would be overcome in time and recovery eventually ensue. The abdominal wound was at this time still draining, but was closing up well.

However, fresh attacks of abdominal pain began and were accompanied by distension of the abdomen, rigidity, and a palpable mass in the left iliac fossa. It was obvious that unless surgery could relieve the abdominal condition recovery was very unlikely. The patient, however, was averse to any operation. His wife, a most intelligent woman, was certain that he would never consent and agreed at once that if an operation could nevertheless be performed that was the right course to pursue. I was asked to see the patient with a view to the possible safe use on him of avertin per rectum. In accordance with the views of his surgeon, Mr. L. E. Barrington-Ward, and Dr. Landale Clark, I explained to the patient that we desired to give him an enema which might have some effect on the bowel higher up. To this he consented. An injection of 4·5 c.cm. avertin in 180 c.cm. distilled water was slowly run in. The patient was encouraged not to object to any feeling of drowsiness that might arise, and he was assured that this was not unusual and betokened no danger. Within 10 minutes he was snoring gently. In half an hour's time Mr. Barrington-Ward opened the abdomen and found, after escape of some free fluid, a couple of coils of small intestine glued together and twisted on themselves with almost complete obstruction of the lumen. The bowel was nearly black but still glistening. A local short circuit was performed and the abdomen closed, and the patient carried back to bed about an hour after he had left it. During the first carrying from bed to operating theatre the patient had wakened up enough to moan at the pain of the lifting, although, of course, no consciousness had returned. During the operation 2½ drachms of C.E. mixture were used to facilitate closing of the peritoneum. Two hours after the time of beginning the operation the eye reflexes were brisk, and it was clear that the patient's state, as far as the anæsthetic was concerned, was one of safe recovery. Shock was not severe and was met by drip instillation of 5 per cent. glucose solution. During the evening and for 24 hours after the operation the patient slept off and on, took nourishment, and complained only of the pain he had experienced on the day before. There was no sickness or nausea. Owing to the daily dressings of the original appendix wound there was of course to him nothing unusual in the abdominal dressings that were carried out. He made no inquiries about what happened after his "enema." There was, as usual with avertin, an amnesia which wiped out time from the start of the injection to many hours after recovery.

Reviewing the facts of this case, the question arises whether any other method would have been possible. The only alternative I can think of is paraldehyde. No inhalation, of course, can be used without the patient's coöperation, and with any local or spinal method he would have realised the operation. A heavy doping with opiates would have been probably fatal to his chest condition. There remain only rectal methods, and of these ether can be ruled out because it would have been recognised and objected to in the early stages. Paraldehyde might have met the case equally well; it certainly could not have surpassed the result achieved with avertin.

THE LYSOZYME CONTENT OF SALIVA IN PSYCHOTICS.

By L. S. Penrose, M.D. Camb.,
RESEARCH STUDENT, CARDIFF CITY MENTAL HOSPITAL.

In his Arris and Gale lecture in 1929 Prof. Alexander Fleming[1] made reference to the discovery of a powerful antibacterial substance, lysozyme, which was present in normal human saliva in sufficient strength to cause, after diluting to 1 in 300, complete solution of a certain staphylococcus, *Micrococcus lysodeikticus* at 45° C. in one hour.

It has frequently been stated that infections of the nasopharynx and alimentary tract are common among patients suffering from mental disease, and causal significance has been attached to them by Cotton,[2] Ford Robertson,[3] and others. The following investigation was carried out to discover whether any corresponding alteration could be observed in the lysozyme content of the saliva of psychotics as compared with the normal. Every subject was investigated three times, over a period of six months, and as the lysozyme content in each case was found to be fairly constant, an average value was taken. The saliva was obtained at midday, centrifuged, to clear the fluid of solid matter, and tested at once. The criterion taken was the highest dilution of saliva giving rise to more than ⅞th lysis of standard buffered suspensions of *M. lysodeikticus* (two days growth on agar) in one hour at 37° C. This was found a convenient method for measuring the strength of lysozyme present. The degree of lysis was judged by comparision with tubes containing barium sulphate suspensions of standard opacity. The following results were obtained:—

Highest Dilution of Saliva Giving Standard Amount of Lysis.

Average of—	
6 normal controls	1/292
8 cases of dementia præcox	1/267
4 mental defectives	1/242
4 cases of mania	1/211
4 ,, post-encephalitic parkinsonism	1/128
6 ,, general paralysis	1/89

No relation between the titre of lysozyme and age could be demonstrated. The actual quantity of saliva secreted was not found to be an important factor. In the above series some of the cases of dementia præcox were very vigorous dribblers like the post-encephalitics. A series of data taken comparing the lysozyme content with the quantity of saliva obtained in three minutes makes this point clear.

Less than 0·5 c.cm. collected (average of 30 tests), titre of lysozyme measured as above	1/144
More than 0·5 c.cm. collected (average of 23 tests), titre of lysozyme	1/172

Males have, as a rule, a slightly lower titre than females (about 20 per cent. less); this is possibly due to the habit of smoking which seems to cause

[1] Fleming, A.: THE LANCET, 1929, i., 217.
[2] Cotton, H. A.: Jour. Ment. Sci., 1923, clxiv., 329.
[3] Robertson, W. M. F.: Jour. Ment. Sci., 1922, lxviii., 8.

secretion of watery saliva. For example, the figures for the four male cases of G.P.I. were 1/117, 1/53, 1/50, 1/117, and those for two female cases were 1/133 and 1/67.

The figures quoted suggest that there is no significant difference between the normals, mental defectives, and cases of dementia præcox with regard to the lysozyme content of saliva, but that in organic psychoses, such as G.P.I. and parkinsonism, the concentration is much diminished. The diminution of lysozyme content appeared connected with a generally weak physical state and low resistance to infection. It is interesting to note that the lysozyme content was uniformly low in parkinsonism, where the infection is supposed to travel via the saliva.

My thanks are due to Dr. M. Penrose for her help and to the Medical Research Council for financial assistance.

ADJUVANTS TO THE MALARIAL TREATMENT OF GENERAL PARALYSIS.

By John H. Ewen, M.R.C.S. Eng., D.P.M.,

ASSISTANT MEDICAL OFFICER, SURREY COUNTY MENTAL HOSPITAL, NETHERNE.

Most authorities agree that, in order to obtain the best results from the malarial treatment of general paralysis of the insane, it is essential to supplement this line of treatment by a course of antisyphilitic remedies. It is not always easy to decide between the rival claims of the various antisyphilitic preparations obtainable, especially in relation to the malaria-infected subject. In four of the following five cases a different antisyphilitic therapeutic agent was used, while all the cases had exactly the same routine malarial treatment. Blood inoculation (5 c.cm.) was employed in every case, and eight to twelve rigors allowed, while throughout the course ℿx. of cardiazol (Knoll) were given thrice daily.

THE CASES DESCRIBED.

Case 1. *Novarsenobillon.*—Male, aged 48. Mental condition before treatment: excited and grandiose; restless and emotional; noisy, destructive, and impulsively violent. Wet and dirty in his habits and confined to bed. A typical case of the classical type. Physical condition: fat and flabby.

Six intravenous injections of novarsenobillon 0·6 g. were given before the malaria inoculation and six after the last rigor.

Mental condition after treatment: quiet and well-behaved; clean in his habits; while his delusions of grandeur persist, they are not so prominent. He is up and about and does a little ward work. Much improved physically.

Case 2. *Bismògenol.*—Male, aged 44. Mental condition before treatment: hypochondriacal delusions and auditory and visual hallucinations; cerebration very slow; confused and at times incoherent. Physical condition: fair.

Sixteen intramuscular injections of 2 c.cm. bismogenol (Tosse) were given before malaria treatment.

Mental condition after treatment: hypochondriacal delusions in abeyance; still hallucinated; on the whole no real mental improvement. Physical health much improved.

Case 3. *Mesurol.*—Male, aged 33. Mental condition before treatment: exalted and egotistical; marked euphoria; excited, restless, and impulsively violent; greatly lacking in insight and full of foolish schemes for money-making. Physical condition: thin and in poor health, with a marked facial tremor.

Eight intramuscular injections of 1 c.cm. mesurol were given before malaria treatment and two injections after the last rigor.

Mental condition after treatment: a marked and definite improvement; quiet and well-behaved and occupies his time usefully; well orientated and in touch with reality. Physically much improved, and has gained over a stone in weight. Facial tremor practically gone.

Case 4. *Tryparsamide.*—Male, aged 49. Mental condition before treatment: typical delusions of rank and wealth; restless, destructive, and excited; exceedingly talkative, with no emotional control. Wet and dirty in his habits and confined to bed. Physical condition: very poor.

Six intravenous injections of 3 g. tryparsamide were given after the last rigor.

Mental condition following treatment: a definite improvement; quiet and well-behaved; no evidence of any delusions; converses rationally concerning his illness, and shows insight and emotional control. Habits clean. Physically: very much improved.

Case 5. *Malaria treatment alone.*—Male, aged 56. Mental condition before treatment: grandiose and religious delusions; auditory hallucinations; noisy, restless, and incoherent. Wet and dirty and confined to bed. Physical condition: marked cardiovascular degeneration.

After malaria treatment he became quieter and better behaved, with some improvement in his habits, but his mental condition is totally unchanged. The malaria does not appear to have affected his physical condition.

CONCLUSIONS.

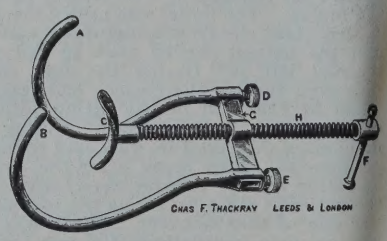
The best result was that obtained from the use of mesurol, but undoubtedly the age of the patient was a prominent factor. Tryparsamide gave a definite improvement with no subjective symptoms, while a promising change for the better was obtained through novarsenobillon. Neither bismogenol nor malaria therapy by itself gave encouraging mental results, although the physical health was improved: All the cases remained Wassermann-fast, and there were no material changes in the cerebro-spinal fluid after treatment. The physical signs in the main persisted.

I am indebted to Dr. P. C. Coombes, medical superintendent of Netherne Mental Hospital, for permission to publish these notes.

NEW INVENTIONS

OSTEOCLAST WITH SCREW CONTROL.

The accompanying figure illustrates an osteoclast the pattern of which is founded on the ordinary steel rail bender. I have had the instrument in use for a considerable time, and am satisfied with its performance. In attempting to straighten deformed bones, to move stiff joints, or to correct such a condition as talipes, manual efforts are futile and exhausting, as so much energy is dissipated in controlling the corrective force. With the screw adjustment (H) the amount of force available is very great, and yet is strictly under control—which is not the case with the lever osteoclast in general use. To minimise injury to the tissues the resisting arms (A and B) and the plunger (C) are encased in thick rubber tubing (supplemented when required with sponge rubber or wool). Less damage to the soft parts results if the pressure is rapidly applied, and the tension removed in a short while by unwinding the screw. The arms (A and B) are adjustable on the bar (G) by the screws (D and E) so that curves of various diameter may be treated. The bar (F) slides in its sockets, so that extra leverage may be applied to the screwed plunger (H). Messrs. C. F. Thackray, Regent-street, London, W., are the makers.



Alexander MacLennan, M.B., C.M. Glasg.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN WINNIPEG.

(*Continued from p. 641.*)

SECTION OF ANÆSTHESIA.

THIS Section met under the presidency of Dr. R. E. APPERLEY (London). At the first session a paper on anæsthesia for

Operations on the Gravid Uterus

was read by Dr. H. W. FEATHERSTONE (Birmingham). A wide choice of methods, he said, was available for anæsthesia in these cases, and thus the anæsthetist could help the obstetrician to guard the pregnant woman against the dangers of her pregnancy. He confined his remarks to those operations normally undertaken to improve the course of pregnancy, or to make unobstructed labour possible. Muscular relaxation and freedom from congestion were necessary, and ether, ether-chloroform mixtures, or spinal anæsthesia gave excellent results. Manipulation of the fœtus in utero required, as a rule, only light and non-toxic anæsthesia, such as that produced by nitrous oxide and oxygen. In general, chloroform was the most useful for labour; it was safe and convenient for midwifery practised outside hospitals. The lightest anæsthesia—just a dreamy sleep or amnesia—should be aimed at, with deepening of anæsthesia for application of forceps. Ether was safe but pungent for the patient. Avertin was the most pleasant anæsthetic, but it prolonged labour, and the duration of its effect was limited. In his opinion, nitrous oxide oxygen was the most satisfactory anæsthetic; a special anæsthetist, however, was necessary, and the heavy weight of the apparatus tended to limit its employment to hospitals and similar institutions.

For evacuation of the uterus and for Cæsarean section, Dr. Featherstone, in conjunction with Prof. Beckwith Whitehouse, had found that spinal analgesia, on account of the strong, continuous contraction of the uterus which it produces, was safe and valuable. He presented an analysis of 100 cases of Cæsarean section performed under spinal analgesia. The loss of blood was remarkably small, the fœtus was lively and free from embarrassment, and the suture line could be inserted firmly. The mothers were all questioned by a recent postal inquiry, and without exception they expressed complete satisfaction. In the attempt to ensure an active child preoperative sedatives were withheld, but nitrous oxide oxygen was frequently administered in addition to the spinal analgesic. Hysterectomy of the gravid uterus in the later stages of pregnancy, usually for toxic concealed accidental hæmorrhage, was an extremely serious operation, and nitrous oxide oxygen anæsthesia gave the best hope of success.

ADVANTAGES OF NITROUS OXIDE.

Dr. SAMUEL JOHNSTON (Toronto) thought nitrous oxide and oxygen was the most valuable anæsthetic for operations on the gravid uterus. In instrumental delivery he always administered an extra amount of oxygen immediately before the birth of the child. His experience was that toxic patients and those suffering from eclampsia, chronic nephritis, and myocarditis had the highest mortality-rate. He regarded chloroform as a dangerous drug, and in no circumstances would he allow a patient to administer chloroform or any other anæsthetic agent to herself. If he were handicapped and had no assistance whatever, he would first administer the anæsthetic himself and then deliver the patient. He preferred ether to chloroform because it was safer, and because anæsthesia was more prolonged. He had used spinal analgesia in selected cases and had found it very satisfactory for diabetics and where goitre obstructed respiration. He did not advocate its employment in cardiac conditions because the drop in blood pressure made it very dangerous. Recently he had obtained satisfactory results from the employment of sodium amytal as a sedative before anæsthesia.

Prof. W. WEBSTER (Winnipeg) said that the best anæsthetic agent for these conditions was one which was rapidly absorbed and rapidly excreted, and the best available were ethylene and nitrous oxide. The use of one of these as an analgesic was probably ideal. His objection to spinal analgesia was that it was accompanied by a contraction of the circular muscle of the uterus which was apt to delay labour.

Dr. M. E. BOTSFORD (San Francisco) regarded a nitrous oxide-oxygen mixture as safest. She did not employ preoperative medication because she considered that it had a deleterious effect upon the child. She used ether in addition if labour was prolonged, but the mother was flooded with oxygen immediately before delivery. The use of sodium amytal was attended with good results to the mother, the condition produced resembling scopolamine-morphine narcosis, but the child had often died.

SAFETY OF CHLOROFORM.

Dr. DAVID LAMB (Glasgow) spoke of the difference between the practice of midwifery in England and in North America. In England, where much domestic midwifery was performed, the administration of nitrous oxide was attended with difficulties which did not apply to hospital practice. For these cases small whiffs of chloroform were given. This was perfectly safe and perfectly effective.

Dr. R. WATERS (Madison, Wis.) said that in rural U.S.A. most women were delivered under chloroform anæsthesia with a feeling of assurance. He disagreed with Dr. Johnston's statement that the anæsthetic agent was the most important factor; in his opinion the anæsthetist was. He considered that spinal anæsthesia should be accompanied by oxygen and carbon dioxide administered by inhalation, because this tended to retain correct alveolar balance.

Dr. J. S. LUNDY (Rochester, Minn.) said that it had recently been shown that chloroform had very little effect upon newly formed liver as contrasted with old. This probably accounted for the innocuousness of the agent when used in labour. He had frequently seen protracted headache, diplopia, and even foot-drop after spinal anæsthesia.

The PRESIDENT commented upon Dr. Lundy's statement regarding the effect of chloroform upon young liver. Some years ago he investigated the effect of this drug upon the liver, and he found that this organ was damaged more in some cases than in others. He felt that Dr. Lundy had supplied the explanation. Whenever possible he used nitrous oxide and oxygen for the type of case under discussion, but he preferred spinal analgesia for those complicated with cardiac disease.

Endotracheal Anæsthesia.

Dr. I. W. MAGILL (London), in a paper on Technique in Endotracheal Anæsthesia, said it was only recently that this form of anæsthesia had been regarded as within the normal routine of the operating theatre. Its advantages were now widely known and, in

England, many expert anæsthetists now employed the method for operations which formerly bristled with anæsthetic difficulties. In some quarters, however, endotracheal anæsthesia was either not available or its administration was attended with unfavourable results; he attributed this to the fact that many anæsthetists would not trouble to master the technique of intubation. The method had many advantages; the airway was free under all conditions, the patient was protected against the entry of blood into the trachea, the surgeon was protected from anæsthetic-laden exhalations, and, because the larynx was under control, it was possible to maintain a light and even anæsthesia. The fundamental principle of the method was the provision of an airway that was practically proof against obstruction. Dr Magill said that, in his opinion, with the exception of those operations in which positive pulmonary ventilation was essential to life, low pressure or no pressure gave adequate results. He stressed the importance of the correct position of the patient's head for intubation. Hyperextension usually augmented the difficulty of the procedure; the head should bear the same relation to the neck and trunk as obtained in the erect position. If a curved rubber tube was now passed into the nostril it would naturally enter the glottis, but if it was passed through the mouth it would almost always enter the œsophagus. When intubating through the mouth he preferred to pass the tube by direct vision with the aid of a speculum. This was easily done under deep anæsthesia such as was obtainable with ether, but it could be done quite easily under light anæsthesia if the pharynx and vocal cords were cocainised before or during induction with a fine nebuliser. This diminished the tendency to reflex contraction of the pharyngeal muscles.

Dr. Magill described a method of blind intubation through the nose, which he regarded as most valuable. It could be performed under light anæsthesia without risk of damage to the teeth or to growths. A piece of curved commercial rubber tubing about ten inches long and $\frac{3}{8}$ inch in calibre was passed through one nostril and the end, which was cut obliquely, was passed into the larynx. This manœuvre was quite easy. A wide tube was used in order to maintain free to-and-fro respiration, and thus it was unnecessary to administer the anæsthetic under high pressure or to pass an expiratory tube. Anæsthesia could be maintained on ordinary inhalation principles, and the system could be open or closed. Low pressure was used as routine, but ample high pressure was available immediately in case of any emergency. In every case the pharynx was packed with gauze to ensure that respiration took place through the nose, and in order to prevent blood from reaching the trachea. Dr. Magill stated that this method was quite satisfactory for children, a smaller tube, of course, being employed.

DISCUSSION.

Dr. WATERS wondered if Dr. Magill had used excess of carbon dioxide in order to separate the vocal cords, and also if he employed morphine or any other premedicament. He did not like the two-tube method because there was a tendency to wash CO_2 out of the body. Like Dr. Magill, he preferred the single tube method; he used a thinner-walled tube than that which had been described. He did not pack the pharynx, but he used a special form of inflatable cuff, which was slipped over the tube.

Dr. R. HARGRAVE (Toronto) said he had never used nasal intubation. He inquired if Dr. Magill passed a tube through both nostrils or whether he only used one nostril. He asked if there was any difficulty regarding preliminary cocainisation.

Dr. J. A. BLEZARD (Edmonton, Alberta) inquired if nitrous oxide produced sufficiently deep anæsthesia for intubation.

Dr. S. JOHNSTON (Toronto) wondered if endotracheal anæsthesia was as safe as had been supposed. He described a case in which sudden cyanosis and death occurred during the endotracheal administration of nitrous oxide and oxygen. The lungs were inflated with oxygen without effect.

Dr. HAYES (Christchurch, New Zealand) asked if Dr. Magill interrupted the flow of gases; also at what stage the tube was removed.

Dr. E. I. MCKESSON (Toledo) believed that nasal intubation had a great future. He once devised a straight tube for its performance; this was not a success; like Dr. Magill's tube it should have been curved. He agreed that the anæsthetist should endeavour to visualise the tip of the catheter. There was plenty of room for improvement in the technique of administration of endotracheal anæsthetics in America.

Dr. LUNDY said that dexterity was the main requirement in passing a nasal tube. He always used a water manometer in connexion with the tube. He believed that sudden pressure on the posterior pharyngeal wall was not devoid of risk; some years ago a patient suddenly died during examination of the naso-pharynx, and death was attributed to this.

Dr. FEATHERSTONE asked if there was any risk of tracheitis. When the tube, in error, was passed into the œsophagus, and the anæsthetic was blown into the alimentary tract, there was the danger of rupturing the wall of a viscus.

Dr. BOTSFORD asked the indications for endotracheal anæsthesia. She described a method of passing the tube indirectly over a stilette, without the aid of a speculum.

Dr. H. SHIELDS (Toronto) was impressed by the simplicity of Dr. Magill's method and by their adaptability for oral and pharyngeal operations. He asked for further information regarding the use of the method in children.

In reply, Dr. MAGILL said he often employed CO_2 to widen the vocal cords. He also premedicated with morphine, hyoscine, or paraldehyde. He did not hesitate to deliver the gas under pressure; neither did he hesitate to use cocaine, for surgeons used it without risk for minor operations about the nose and throat. He had cocainised young children. He liked to have an active cough reflex before withdrawing the tube. There was no reason why two tubes should not be used—one for each nostril. Tracheitis could be prevented if the tubes were well lubricated with sterile paraffin.

Post-operative Pulmonary Complications.

At the second session the chair was occupied by Prof. W. WEBSTER (Winnipeg), Vice-President, and Dr. D. C. AIKENHEAD (Winnipeg) read a paper on Post-operative Respiratory Complications during a Four-Year Period. He analysed the lung complications following 33,066 operations performed during the years 1926–29. Of these, 31,301 were performed under general anæsthesia, while the remainder were under some form of local anæsthesia. According to the records there were 55 cases with respiratory complications with 23 deaths.

Dr. Aikenhead detailed the preoperative routine for these patients. Perhaps 65 per cent. would receive morphine sulphate gr. $\frac{1}{6}$ with atropine sulphate

gr. 1/150. Operation was postponed in patients with coryza or with a history of respiratory trouble. Over half the series received open ether, and approximately one-sixth received nitrous oxide or ethylene. Operations performed included all types and the age limits were four days to 90 years. Of the 55 respiratory complications, 13 were of a minor nature, while the remaining 42 were pneumonic processes. Of these 42, 19 cases had gross sepsis present at operation and 14 (or 73 per cent.) died. The incidence of respiratory complications was approximately equal for both sexes, while each decade over 40 added to the risk. A curious feature was that gas anæsthesia carried a higher rate of pulmonary complications than ether, probably because this was the anæsthetic of choice in handicapped patients. Dr. Aikenhead considered that the splinting of the abdominal muscles by pain and tight binders predisposed to circulatory stasis in the bases of the lungs. Infection tracked up to this area of stasis through the diaphragm via the lymphatics. He concluded that a post-operative respiratory complication was a serious hazard to recovery, but that, taking into consideration the number and gravity of modern surgical procedures, pulmonary complications followed operations less frequently than might be expected. Gross sepsis at the time of operation predisposed to post-operative pneumonia, but the careful selection of patients for operation with equal attention in the after-care could minimise the risk of a respiratory lesion until such time as a more definite cause for this complication is known.

The PRESIDENT (Dr. Apperley) congratulated Dr. Aikenhead upon his paper and upon the magnitude of his figures. In 22 years he had given 37,000 anæsthetics to patients varying in age from 18 hours to 96 years. In the old days, it was not uncommon to see a mild form of post-operative pneumonia which was abolished largely by the introduction of atropine. The routine in England was to premedicate all patients with atropine gr. 1/100, and this reduced post-operative respiratory complications except, perhaps, in upper abdominal operations. He had observed that nose and throat operations were singularly free from these complications, and he held the view that the inhalation of septic material was not, in itself, a cause of respiratory complications. With the possible exception of radical hysterectomy, pelvic cases were almost always free from these complications, and he considered that this reduction was due to the introduction of spinal anæsthesia, which reduced the time the patient was upon the table. In his experience, operations upon the upper abdomen were those most commonly followed by respiratory complications. He concluded that there was no routine method for prevention, but that each case must be considered individually.

Dr. F. J. G. LA FLECHE (Winnipeg) said that lung complications should be regarded as post-operative rather than post-anæsthetic. Incidence was due to many factors: the patient's preoperative condition, premedication, the site of operation, the handling of the tissues, the kind of anæsthetic, the interference with the respiratory and circulatory functions, the reduction of vital capacity following operations, and the post-operative care. All these factors combine to reduce the patient's vitality, so that latent respiratory infections might develop into serious trouble. The use of CO_2 and O_2 would more thoroughly help to prevent atelectasis and stasis.

Dr. FEATHERSTONE said some years ago he analysed 4 different ætiological factors for post-operative pulmonary complications. He considered that upper abdominal operations, shock, and infection were the most important factors. Including terminal pneumonia, the pneumonia-rate was about 1 per cent. of all surgical procedures, but his impression was that it is now less common than ten years ago. At the end of the war, the incidence of these complications rose markedly in Vienna, probably because of defective nutrition.

Dr. LAMB said some years ago he analysed a series of post-mortem reports and, in every case of post-operative pneumonia, there was an associated septic condition. There was extreme danger in operating upon a patient with coryza. Dr. Lamb referred to the frequency of lung abscess following tonsillectomy in America as contrasted with the infrequency of this condition in England.

Dr. JOHNSTON said the probable explanation of Dr. Lamb's observation was that tonsillectomy was usually performed in the recumbent position in England and in the sitting position in America.

Dr. BOTSFORD stressed the importance of eradicating all throat infections before submitting the patient to operation. She had found that respiratory complications were reduced when tonsillectomy was performed under nitrous oxide and oxygen. Although chloroform was dangerous for the heart, it was safer than ether for the lungs.

Prof. WEBSTER described the "leaning forward" position for tonsillectomy; the recumbent position was adopted for this operation in Winnipeg. He considered the depth of anæsthesia to be an important factor in respiratory complications; inhalation of pus and blood occurred when anæsthesia was sufficiently deep to relax the soft palate. These complications were very frequent when tonsillectomy was performed under local anæsthesia.

Dr. MCKESSON did not consider the anæsthetic or the position exclusively responsible for respiratory complications. Many factors were concerned. He had given 1000 nitrous oxide and oxygen anæsthetics for tonsillectomy with only one lung abscess; this occurred in the practice of a surgeon who demanded deep anæsthesia and got it. In tonsillectomy the patient should be kept light and the airway free.

Dr. BLEZARD had a great regard for atropine, and felt that it might be used post-operatively.

Dr. HAYES said that in New Zealand he had never seen a lung abscess after tonsillectomy.

In reply, Dr. AIKENHEAD said that in North America there were a great many cases of sinus infection which, no doubt, predisposed to respiratory infection. He agreed that adequate preoperative medication was essential.

Sodium Amytal.

Dr. L. G. ZERFAS (Indianapolis) read a paper on Sodium Amytal. This drug, he said, which chemically was sodium iso-amyl-ethyl barbituric acid had, in common with other barbiturates, hypnotic properties; The barbiturates, however, differed largely as to toxicity, rate, and manner of elimination. The therapeutic margin of safety had been determined for a great many of these compounds, and it had been found that it was, approximately, in proportion to the fatal dose. Amytal was rapidly and completely destroyed in the body, for no trace of the drug or its decomposition products could be demonstrated in the urine after intravenous administration. No investigations had yet been made concerning the possible excretion of the drug in the fæces, its content in the body tissues, or its rate of disappearance from the blood stream. Amytal had little or no effect upon metabolism;

carbohydrate metabolism was not affected in the same chaotic manner as by ether, and it had been shown that sodium amytal prevented the hyperglycæmia which normally followed the injection of morphine in dogs. The intravenous injection of sub-lethal doses of sodium amytal produced an alarming fall of blood pressure if the drug was given rapidly. Not more than one grain should be injected per minute. The average systolic fall in man after normal injections was 30 mm. Hg. Patients with hypertension suffered a greater proportionate decrease. In animals toxic doses of sodium amytal usually caused death by respiratory failure; with normal doses, however, the respirations were reduced in amplitude, but their regularity was maintained. After the intravenous introduction of grs. 3 to 9 to man drowsiness and profound sleep came on quickly. The corneal reflex was diminished, but the gag reflex remained. Unconsciousness lasted three to six hours.

Dr. Zerfas felt that it was safer to use sodium amytal by the oral or rectal routes rather than intravenously. There was no fixed rule for dosage. He regarded grs. 15 as the maximum dose. There was ample evidence that sodium amytal was useful as a pre-anæsthetic hypnotic; but it should not be regarded as an anæsthetic agent.

Dr. LUNDY said he regarded the oral dose of sodium amytal as grs. 16 to 45. Larger doses were toxic to the patient. He had seen grs. 3 per hour given to a patient with convulsions for several months. Altogether, grs. 9000 were administered without toxic manifestations. The exhibition of sodium amytal was contra-indicated in comatose cases. In common with other barbiturates, toxic doses caused acute pulmonary œdema which was best treated with intravenous hypertonic glucose solution and an oxygen tent. In some cases sodium amytal produced excitement instead of narcosis; this was probably due to the production of isomers which possessed a different effect. He considered that sodium amytal should be regarded as an hypnotic rather than as an anæsthetic.

Dr. BOTSFORD described the effects of sodium amytal upon a series of children. She stressed the fact that it abolished the dread of operation with its subsequent production of various mental complexes. The use of premedicaments such as sodium amytal tended to abolish fear; in addition, it rendered possible the use of much smaller quantities of inhalation anæsthetic. She administered the drug orally in capsules. She concluded that sodium amytal could safely be given to children; that it was more effective than opium in abolishing fear; and that the minimal effective dose should be administered by mouth.

Dr. MOORE (Grand Forks, N. Dakota) described good effects from the use of sodium amytal in obstetrical work. He administered the drug by intramuscular injection and labour, or even a low forceps delivery could be conducted without the use of any other anæsthetic. In no case had the patient complained of after-pains, and, in reply to Dr. Featherstone (Birmingham), Dr. Moore stated that he had observed no untoward effect upon the child.

Dr. BLEZARD also described good results from the use of sodium amytal in labour. The drug appeared to relax the cervix.

Dr. F. B. PARSONS (Cambridge) maintained that sodium amytal and, indeed, all so-called non-volatile anæsthetics, should be regarded as premedicaments, and not as anæsthetics. It was impossible to control the action of these drugs upon a patient, and for this reason he expressed the view that future developments would take place in the direction of the better administration of inhalation anæsthetics. The dosage of sodium amytal appeared unsatisfactory; he had heard recommended doses of from grs. 3 to grs. 45 for an adult patient. This has rather a large range for a barbiturate.

In reply Dr. ZERFAS said that sodium amytal and other non-volatile anæsthetics should not be used in routine fashion. They were valuable, however, for those patients who were psychically disturbed at the thought of an inhalation anæsthetic.

SECTIONS OF RADIOLOGY AND OTO-LARYNGOLOGY.

AT a combined meeting of these Sections, Sir STCLAIR THOMSON being in the chair, a discussion on the

Mechanism of Swallowing

was opened by Dr. A. E. BARCLAY (Cambridge), who gave an account of the observed mechanism of swallowing. All the evidence, he thought, pointed to the fact that the bolus of food was carried from the back of the tongue down the œsophagus as far as the clavicular level by negative pressure. He showed photographs of food passing down the first part of the œsophagus. The fact that the bolus was in no way compressed showed there was no pressure from behind. The negative pressure in the pharynx was produced by a combined raising of the larynx and backward movement of the tongue, which together obliterated the pharyngeal space for a fraction of a second. With mouth, nose, and larynx closed, the reopening of the pharynx produced a negative pressure that was largely responsible for the act of swallowing. Except for fluids, gravity played a minor part in the normal act. The larynx was cut off, not by a movement of the epiglottis or of the laryngeal margin, but by a dragging up of the laryngeal pharynx behind the larynx to touch the epiglottis not far below its tip. He summed up the phases of swallowing as follows:—

1. The mouth and nose are closed.
2. The larynx is raised and closed and its upper part is obliterated by the back of the tongue.
3. The pharyngeal space is obliterated by (*a*) raising the larynx; (*b*) retraction of the tongue. (The posterior wall of the pharynx does not come forward—the pharynx is not constricted, but is compressed from before backwards against the posterior wall—i.e., against the vertebræ.)
4. The pharynx is opened up and with the three outlets closed a negative pressure is obtained by (*a*) dropping the larynx; (*b*) allowing the tongue to go forward.
5. During this movement the laryngeal pharynx still remains high up, in close relation to the epiglottis. It is in an opened-mouth condition.
6. Food is tipped over the back of the tongue.
7. Food is sucked into the open mouth of the laryngeal pharynx, which, as it receives the bolus, drops from the epiglottis down to its normal position, thus opening up the larynx again, after the food has passed.
8. The food is probably sucked some distance down the œsophagus.

Dr. L. J. CARTER (Brandon) remarked on the difficulties of investigation owing to the exceedingly short space of time occupied by the act of swallowing. Dr. Barclay's work illustrated the value of serial radiography.

Mr. E. D. D. DAVIS (London) said that the epiglottis could be removed without causing a patient difficulty in swallowing. It was the vestige of a structure designed to direct the air current into the nasal pharynx and had become modified for the production of speech. Swallowing was a combination of negative

air pressure and muscular action; this was shown by the inability to swallow when the muscles of the pharynx were paralysed.

Benign Gastric Tumours.

In opening the discussion on this subject Dr. W. H. DICKSON (Toronto) gave a résumé of the types of benign tumours found in the stomach, beginning with the different gastric polypi. Single tumours included myomas, fibromas, neurocytomas, angiomas, and lipomas. In all these cases there was no marked induration to be felt; the stomach should always be palpated during the screening. Syphilitic conditions were found not uncommonly at operation, although not nearly so often as malignant diseases.

Dr. BERNARD MOONEY (Edmonton) said he had looked up records of the four general hospitals in Edmonton. After excluding inflammatory masses of a syphilitic character and those due to ulcer, no single cases of benign gastric tumour remained. The rarity of the condition was also borne out by the published statistics of James Douglas. The only case in his own experience was that of a simple fibroma removed from the duodenum, which had a pedicle extending up through the pylorus.

X Ray Diagnosis in Medico-Legal Cases.

Dr. A. HOWARD PIRIE (Montreal) described the pitfalls into which the practitioner might fall in giving evidence before the courts, and showed by lantern slides how easy it was to mistake an abnormal bone or the abnormal development of a bone for a fracture. Such abnormalities being frequently bilateral were shown up by taking a skiagram of the opposite side. He gave a useful table of the average number of days necessary for convalescence following fracture of various parts of the body.

Dr. E. E. SHEPLEY (Saskatoon) said it was advisable to secure plates immediately in all cases of accident, for a slight trauma was sometimes sufficient to activate a quiescent pathological condition, such as osteo-arthritis. In this way employers of labour were frequently held responsible for conditions alleged to have been caused by serious injury when in reality the disability was already existing in a dormant state at the time of the accident.

Dr. FRANK A. SMITH (Winnipeg) thought the interpretation of skiagrams should be left to medical men skilled in radiology.

X Ray Therapy.

Prof. J. E. GENDREAU (Montreal) dealt with the possibilities of high power X ray therapy. He showed slides of a tube constructed to withstand 900 kilo-volts; this could only be employed in a laboratory, but it was possible to use tubes for therapeutic purposes which would withstand 350 kilo-volts. With such a tube the average wave-length was more penetrating than the maximum penetration given by a tube with 250 kilo-volts. He believed that more powerful tubes would soon be in use for therapy, even up to 600 kilo-volts.

Radium in Cancer Therapy.

Dr. DOUGLAS QUICK (New York) surveyed the present use of radium in cancer therapy and its relation to operative surgery and X ray therapy. Accurate application and adequate dosage were essential for effective treatment, and he outlined the work being done at the Memorial Hospital to estimate dosage more exactly. The relative radio-sensitivity of the tumour as determined by careful histological studies should, he said, be taken into account when irradiating it.

Prof. JAMES EWING (New York) said he was hoping for improvement in another direction—namely, by increasing the radio-sensitivity of tumours, e.g., by the injection of heavy metals. In some tumours the object of treatment was to destroy the malignant cell; in others, especially where there was a large mass of tissue, beneficial results might be due to a change in the character of the cell which deprived it of its malignant characteristics.

IN MENORRHAGIA.

Dr. MALCOLM DONALDSON (London) spoke of the importance of radiotherapy in non-malignant conditions, especially for the distressing attacks of irregular hæmorrhage associated with the onset of the menopause. It was, of course, essential to exclude malignant disease before attempting to treat such a case. In the case of irregular hæmorrhage an exact diagnosis could only be made after exploration of the uterus under an anæsthetic. In the case of a woman over 40 years of age, the advantages of radiotherapy far outweighed the disadvantages; in young women the problem was not so simple. It was true that in a certain number of them radium or X ray treatment given in small doses had restored the menstrual cycle to normal and diminished the amount of loss. The risk of producing a permanent amenorrhœa with the accompanying symptoms of the menopause was, however, too great to justify such treatment in young women, and he preferred hysterectomy. Radium, he thought, acted on the ovaries rather than on the endometrium. He advocated radiotherapy for fibroids not larger than a fist when the patient had reached the age of 40. In patients over that age practically every case was cured.

Dr. E. W. PROUD (Vancouver) said he had got satisfactory results with smaller doses than those used by Dr. Donaldson.

IN EPITHELIOMA OF THE SKIN.

Dr. W. ROY WARD (London) dealt mainly with basal-celled epithelioma, and touched only briefly on squamous epithelioma, as the treatment of the latter was surgical. Radium, he said, was undoubtedly the best treatment in most cases of rodent ulcer; cosmetically, it gave results which could not be obtained by any other method. On an analysis of nearly 1800 consecutive cases treated at the Radium Institute of patients whose lesions had become refractory to previous X ray treatment nearly half were healed as the result of radium therapy. Occasionally an undoubted basal-celled growth took on the characteristics of a squamous-celled epithelioma; more than half of these cases were situated in the neighbourhood of the ear. In squamous epitheliomata of the skin the results of excision were so good that radium should be reserved for the more extensive cases or those in which operation was contra-indicated. The treatment of the primary lesion was usually satisfactory; prophylactic irradiation of the neighbouring lymphatic areas was of doubtful value. When the glands were definitely invaded, the immediate result was often encouraging, but the permanent disappearance of infected glands was exceptional.

Dr. PIRIE said that in his own practice X rays had proved as efficient as radium, and the treatment only lasted three minutes.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

THIS Section met under the presidency of Mr. COMYNS BERKELEY (London), and at its first session a paper on

Radium in Gynæcology

was read by Dr. SIDNEY FORSDIKE (London). It was urgently necessary to decide, he said, how radium acts—whether on cell or stroma. While histology showed the change of structure in a tissue after irradiation, it told nothing of why the change occurs. He pleaded strongly that some of the radium at present being provided for clinical research should be devoted to the equally important field of biological investigation. In his own opinion the primary action was on the stroma and the cell changes were only secondary, but further investigation was needed, for it was only by full understanding of this problem that dosage and methods of application could be placed on a scientific basis. The marked divergence of views on screens, split dosage, and treatment of glands demonstrated the present uncertainty.

Whatever its effect on cancer, there was no denying the value of radium in producing an artificial menopause. Even here, however, there were differences of opinion about dosage, and whether the endometrium or the ovaries are affected. Recently, he had himself been using a dosage of 53 mg. radium element screened by 1 mm. of platinum for 22 hours, and had observed satisfactory results. In his opinion there was no doubt that the ovaries were unaffected, and that all the results arose from the action of radium on the endometrium. Except in very rare cases he did not advocate the use of radium in the treatment of fibroids.

Dr. Forsdike reported his results in treating 181 cases of carcinoma of the cervix from 1921–25 as follows: inoperable cases, 134, alleviation and prolongation of life, but no cure; borderline cases 33, four cured; operable cases, 14, four cured. The rate of cure in all cases treated by radium was 4·5 per cent., and even in operable cases only 28 per cent., and though he was a believer in the value of radium after research had cleared up many points, at present he thought that in malignant cases operation gave the best results, and he foresaw a general resumption of operative treatment.

Prof. W. CHIPMAN (Montreal) agreed with Dr. Forsdike in his plea for more knowledge in the treatment of carcinoma of the cervix by radium. In cases of uterine hæmorrhage radium was most useful where hæmorrhage was intrinsic, especially in fibrosis and chronic subinvolution of the uterus, which were usually the result of mild sepsis. Radium could also be used in some cases of fibroids, and in a few extreme cases of adolescent hæmorrhage which had defied other treatment. Prof. Chipman believed that radium has some effect on the ovary. It should not be used in chronic inflammatory disease of the appendages. He suggested the following dosage: in adolescent hæmorrhage, small doses—e.g., 400 mg. hours; in fibrosis 1200–1600 mg. hours; in fibroids 3000 mg. hours. In Montreal the Stockholm technique was used for the treatment of carcinoma of the cervix, and in the last ten years 289 patients had been treated, of whom about 20 per cent. were alive five years afterwards. He thought that all cases of carcinoma of the cervix were best treated by radium. The primary mortality was only 7 per cent., as against 10 per cent. in operation.

Dr. MALCOLM DONALDSON (London) read a communication on

TREATMENT OF LYMPHATIC GLANDS IN CARCINOMA OF CERVIX

He pointed out that while the original growth responded, as a rule, to radium treatment there had not been the same satisfaction in the treatment of glandular metastases. This might be due to insufficient irradiation, and he had, therefore, devised a method of direct application of radium to the pelvic glands in cases of carcinoma of the cervix. The glands seemed to be more resistant to radium than the original growth, and he suggested that they act not as areas of resistance to generalised metastatic spread but actually as centres in which malignant cells can grow more rapidly. This view, he contended, was supported by the fact that while cancer cells were found in the lymphatics it was not until the glands were reached that any large mass of cancer appeared; moreover, it had been shown that tonsillar extract contained a definite growth-producing substance for tissue culture. It had to be considered whether radium acts by direct effect on the cells, or whether its effect is indirectly due to its action on surrounding cells. If the action was indirect, then it might well mean that the effect on glandular metastasis is far less than on other cells of the body. He described his technique for dealing with glands. He had treated 38 cases on these lines, but was not yet ready to pronounce definitely on the value of the method.

DISCUSSION.

Sir EWEN MACLEAN (Cardiff) laid stress on the perils of indiscriminate use of radium, and urged that it should only be employed by those with special training and experience.

Dr. DONALDSON, in discussing Dr. Forsdike's paper, said that there was urgent necessity for further laboratory work. He did not agree that radium had no effect on the ovaries. The artificial menopause it produced was evidence of ovarian destruction. He thought Dr. Forsdike unduly pessimistic about radium treatment.

Mr. GORDON LUKER (London) held that the Wertheim hysterectomy is the best treatment of carcinoma of the cervix whenever possible. In doubtful cases he employed surgery if the condition was improved by one dose of radium. In frankly ineradicable cases he used radium.

Dame LOUISE MCILROY (London) favoured radium treatment rather than surgery, especially because it conserved the uterus. She agreed that the use of radium should be limited to specialists, and thought it should be followed by X ray treatment. Before treatment every case should be investigated pathologically and biochemically. She found that pyometra might follow treatment. She had tried Dr. Donaldson's method of treating lymphatic glands, but had given it up.

Mr. T. G. STEVENS (London) advised avoidance of radium emanation tubes at all costs, for they rapidly lost their power. He had had no success with radium in the treatment of uterine hæmorrhage in young women. He was sure its action was on the ovaries; destruction of endometrium made no difference. He quoted a case of fibroids in which destruction of the ovaries followed insertion of radium into the rectum for rectal carcinoma.

The PRESIDENT said he had been a pioneer both of Wertheim's methods and of radium. He thought the position of radium was not yet determined, and could only be decided by an analysis of cases after at

least ten years. All reports should be along similar lines, and with corresponding records. The best results had been produced by the Stockholm clinic, but the published results of authorities varied enormously. It was difficult to compare them because the standard of cure has not been determined.

The Placental Hormone Emmenine.

Prof. J. B. COLLIP (Montreal), in opening a discussion on this subject, said that the human placenta contains at least three distinct active principles or hormones. These three substances were alike in that all have been observed to be œstrogenic in the immature female rat. The active principle present in the second fraction (85 per cent. alcohol soluble), called emmenine, was very similar to œstrin in its ultimate physiological effects. It was ineffective, however, in the castrate, and hence it might be concluded that it functions directly or indirectly by stimulating the intact ovary. Also it differed from œstrin in the degree to which it is effective by oral administration. The third fraction, prepared from the alcohol insoluble material of the original extract, was similar to the other two in that it is œstrogenic. It differed from the emmenine fraction on three main points: (1) it is ineffective by the oral route; (2) it produces corpora lutea in the immature rat coincident with induced œstrus; (3) it causes an increase in the rate of growth of the sex glands in the immature male. As yet, Prof. Collip had been unable to obtain with surety from pig and cow placenta any of the above fractions other than œstrin. This observation, which must be studied further, suggested that in the human placenta there are hormones which are absent in lower mammalian forms. This suggestion was supported by the observation that pregnancy urine of certain of the lower forms has failed to give an Aschheim-Zondek pregnancy test when injected into immature mice.

The two œstrogenic placental hormones other than œstrin (theelin) appeared to be the counterparts respectively in placenta of prolan A (œstrogenic) and prolan B (œstrogenic and luteinising) of urine described by Zondek and Aschheim. Prof. Collip was of opinion that these active principles are the specific products of placental tissue function and are actively related to the condition of pregnancy. The functional inter-relationship which must exist between the pituitary sex hormones and those of the placenta could only be conjectured at present. Through the kindness of the Medical Research Council and the National Institute for Medical Research he had recently been given facilities to repeat much of the work outlined in Dr. H. H. Dale's laboratory in Hampstead.

Dr. A. D. CAMPBELL (Montreal) gave the clinical results of the exhibition of emmenine in various gynæcological conditions. He considered that the periodicity of menstruation is due to extract of the anterior pituitary gland. It was believed, he said, that ovulation took place on the fourteenth day after onset of the menstrual cycle. The escaped ovum had no effect on the corpus luteum until it became fertilised. Alterations in menstruation were usually due to ovarian derangements. Dr. Campbell had found that emmenine did not disturb the menstrual cycle in normal people. Treatment of amenorrhœa, either primary or secondary, did not give any appreciable results. Cases of polymenorrhœa—i.e., those in which menstruation occurred too frequently—were improved, in that the intervals were increased. He had achieved the best results in dysmenorrhœa, which was often relieved, though it sometimes tended to recur on cessation of treatment. He had done no good for disturbances of the menopause in cases where amenorrhœa had been present longer than 12 months. Emmenine had never produced abortion in pregnant women.

Prof. CHIPMAN pointed out that this work was in a very early stage, and much remained to be done. He thought that the ovarian hormone was stored in the placenta, and was not produced in situ. Cases of ovarian deficiency were very difficult to treat, because of the mental state associated with the physiological conditions. A good deal of emmenine was available for experiment.

Prof. V. J. HARDING (Toronto) said there was some confusion between the various substances found in the placenta; he thought it was open to doubt that they were produced in situ. Emmenine differed markedly from other organic extracts in that overdoses had no appreciable effect. He found that it had an effect in vomiting of pregnancy which was not entirely mental.

The PRESIDENT spoke of the value of Prof. Collip's work on insulin and parathyroid. Although the present investigations were at a very early stage they were likely to give rapid results under Prof. Collip's guidance.

Prof. COLLIP, in reply, said that a simple explanation of the presence of emmenine in the placenta was that it is produced there. Its presence in other tissues had not been investigated, but it was quite possible that it might be found therein, just as œstrin was. An important fact was that it is active by mouth, and he thought it should be possible to make a preparation for subcutaneous injection. He had found that emmenine has no effect on the male.

Prolapse.

Mr. STEVENS (London) gave a demonstration on the operative treatment of prolapse. He said that in this condition operation had not given the high level of cures achieved in other spheres, and he considered this was because many operators are not fully cognisant of the anatomy of the pelvic floor. After referring to the excellent description given by Hart and Barbour, he said that he based his operation on that described and perfected by Donald and Fothergill of the Manchester school. The foundation was to start repair at the top of the vagina instead of the bottom. He did not amputate the cervix as often as was recommended by the Manchester school, though as a preventive of cancer he regarded this as a very valuable procedure. Abdominal operation was rarely needed to complete the cure. Operative mortality with vaginal operation alone was practically nil. The post-operative treatment was very important, and in his cases he directed the installation of ʒii of flavine solution into the vagina daily.

The PRESIDENT said he had done a similar operation many times, and was convinced of its curative value. In his experience there was often a certain amount of superficial sepsis in the skin of the perineum, but he agreed with Mr. Stevens that serious deep sepsis was rare. He had seen two cases where the ureters were included in the deep sutures at the side of the cervix.

Dr. C. D. LOCHRANE (Derby) said he had done Fothergill's operation many times, and could not understand why it was not more universally performed. Apparently it was not nearly so popular in Canada as operations of the Mayo-Ward or interposition type.

Prof. J. FRASER (Montreal) said that he did a similar operation and did not have much trouble

with sepsis. He did not disturb the bladder at all, and kept a catheter in during the post-operative treatment. In subsequent parturitions he believed in doing a lateral episiotomy.

Mr. STEVENS, in reply, said that there was sometimes slight superficial sepsis of the perineum after operation. He had never seen any trouble with the ureters. He always did a central episiotomy in subsequent parturition, and had never seen any harm result.

Analgesia and Anæsthesia in Childbirth.

Dame LOUISE MCILROY said that in England at present there was much interest in the prevention of pain in childbirth. Funds were being raised for the establishment of special resident anæsthetists in the maternity departments of the large hospitals in London. The medical profession was anxious to relieve suffering, but painless labour could not be achieved artificially without some risk to the mother and more to the child. Anæsthetics were always given in maternity operations and, as a rule, in complicated deliveries, but it was clear that more could be done to relieve pain of normal labour. If every woman was to have an anæsthetic longer attendance by the medical practitioner would be required, and, therefore, more expense. Anæsthetics always tended to prolong labour, and skilled anæsthetists would be required to assist at the confinement. Discussion centred round the question which drugs were suitable as sedatives during the stages of labour and which was the most suitable anæsthetic for delivery. Dame Louise had employed drugs extensively for the relief of pain, and she felt certain that they diminished fear and shock and are, therefore, a factor in reducing mortality. Operative interference was also prevented by analgesics for the patient, and her relatives were not harassed by the sufferings of a prolonged labour.

Morphia in small doses was highly beneficial, but had to be used with caution since it might have a harmful effect upon the child. It was frequently combined with scopolamine, but twilight sleep was seldom fully induced in England, because it required special skill and special surroundings. Chloral hydrate with or without potassium bromide was the favourite sedative in use, because it was safe and easy to give. For the second stage of labour chloroform or ether was given at intervals with deeper anæsthesia during actual delivery. The majority of obstetricians preferred ether, but chloroform had many advocates, especially in Scotland. Chloroform was unsafe in cases of toxæmia, such as eclampsia, or in heart disease; ether was irritant in its effect on the lungs; and the safest and best anæsthetic was nitrous oxide gas and oxygen. This must, however, be given by a trained anæsthetist, and needed cumbersome apparatus. Various local and spinal analgesics were being employed by obstetricians, and opinions differed on their advantages and disadvantages.

Every maternity case, said Dame Louise, must be given individual attention with regard to the sedative and anæsthetic employed. Age, parity, temperament, general health, and complications (if any) must all be carefully considered. Furthermore, the effect of sedatives on the child must be taken into consideration. Light anæsthesia was generally employed in midwifery practice except where operative interference was required. The action of the uterus must be maintained, and hæmorrhage after delivery must be prevented as far as possible. Time and money were a difficulty. It was desirable that private patients should have the continuous attendance of the practitioner during labour if sedatives or anæsthetics were to be given, just as in hospital practice; yet it was impossible to demand this unless adequate financial payment was made.

Dr. HENDERSON (Ignace, Ontario) said that since he began practice he had used chloral throughout labour and had found it very valuable. He did not think that the administration of chloroform was dangerous. He had only had three maternal deaths in over 2000 cases, and none of them was due to chloroform.

Dr. M. MACKELLAR (Gwalior) said she had practised in India for 37 years, and had always used chloral and chloroform without a death in delivery.

Dame LOUISE MCILROY showed two cinematograph films of (1) the classical operation of Cæsarean section performed at the Royal Free Hospital; (2) method of resuscitating the new-born in a case of asphyxia after forceps delivery there.

REVIEWS AND NOTICES OF BOOKS

Rose and Carless' Manual of Surgery.

Thirteenth edition. By CECIL P. G. WAKELEY, F.R.C.S., F.R.S. Edin., Surgeon, King's College Hospital; Lecturer in Surgery, King's College Medical School; and JOHN B. HUNTER, *M.C.*, M.Ch., F.R.C.S., Assistant Surgeon, King's College, Hospital, and Lecturer in Surgery, King's College Medical School. London: Baillière, Tindall and Cox. 1930. Pp. 1592. 30*s*.

To have collaborated in the writing of a text-book on surgery, to have kept it abreast of current surgical thought and progress during no less than 32 years, and to retain its position as a favourite amongst students, is no mean accomplishment. This Albert Carless has achieved. In the thirteenth edition he hands over his position of editor-in-chief to his able collaborator in the preparation of the last two editions, Mr. Cecil Wakeley, who has in turn enlisted the help of Mr. John Hunter. Those who have taken no part in such work can only faintly discern how onerous is the task of editing a text-book of modern surgery; but Mr. Carless will have a reward, for he will take with him in his retirement the well-wishes and gratitude of multitudes of medical men in all parts of the world, whose first introduction to surgery was rendered easier by his labours.

The reputation of "Rose and Carless" will not suffer at the hands of the new editors; in this edition, at least, it is well maintained, for the book is thoroughly up to date, and where innovations have been made the spirit of the conception of the original book seems to have been preserved in the judicious selection of subject matter and depth of detail presented. There are, of course, some omissions; a captious critic might find a number, but he would be bound to admit that any student who reads and knows this book will have a thoroughly good ground-work on which to base that more profound knowledge which will only come with the practice of his art. The illustrations are not as good as the text. Some, such as Fig. 461, are unsatisfactory because of the imperfections of the blocks or paper on which they are printed; others are out of drawing, such as Fig. 1, Plate VII., or

untrue to life as Plate XIV., where the disparity in size and vascularity of the entering and emerging segments of intestine is not sufficiently emphasised. The artist who drew this latter picture can surely never have seen an actual strangulated hernia. These are not serious blemishes upon a notable work wherein the new editors have upheld the traditions of one of the finest single-volume text-books of surgery in the world.

Recent Advances in Chemotherapy.

By G. M. FINDLAY, O.B.E., M.D., D.Sc., Wellcome Bureau of Scientific Research. London: J. and A. Churchill. 1930. Pp. 532. 15*s*.

THE word chemotherapy always arouses pleasant anticipation in the medical man's mind, possibly because the discovery of a specific chemical remedy for each disease is the ideal at which everyone is aiming. It was the discovery of salvarsan which proved what a wonderful advance in treatment chemotherapy could bring, and stimulated an interest in the subject which is not likely to fade.

This newest member of the "Recent Advances" series is much larger than some of its predecessors, containing some 500 pages. It is, indeed, almost too detailed, for it is not easy to read. As a book of reference, however, it forms about the only thorough work of its kind in England, and is almost a counterpart, although not so large, of Fraenkel's "Die Arzneimittel-Synthese." The book is divided into chapters, each of which deals with the chemotherapy of a different disease. There are chapters on malaria, syphilis, leprosy, tuberculosis, cancer, &c., all of them well and clearly written. It is doubtful whether some of the chemical formulæ are altogether necessary, and their omission would have helped to lighten the reader's task. Dispersed throughout the book are pictures of the prominent workers in this field, the opening one being of Ehrlich and his assistant. The references and index are very full and the book forms a valuable work of reference.

Recent Advances in Physiology.

Fourth edition. By C. LOVATT EVANS, D.Sc. Lond., F.R.C.P., F.R.S., Jodrell Professor of Physiology and Fellow of University College. London: J. and A. Churchill. 1930. Pp. 442. 12*s*. 6*d*.

Prof. Lovatt Evans in this fourth edition has chosen wisely what to include and what to omit. The contents embrace the physiology of muscle and nerve, labyrinthine function and conditioned reflexes, together with a study of the blood and the capillary circulation. The most recent information is given in regard to the more important hormones; and two new chapters have been added, dealing with the coronary circulation, and the work of Heymans which throws light on the part played by the carotid sinus in the control of the circulation. The subject matter is well presented, and the author has not hesitated to delete such material as is not of topical interest. Much of the earlier work has been rewritten and brought into line with recent researches. The physiology of muscle and nerve is treated very fully, but this portion of the work might be condensed and so leave room for a chapter on the physiology of mineral metabolism, a subject now recognised as very important. On page 421 it seems that the author has not fully acquainted himself with the most "recent advances" in the ætiology of milk fever in cows.

This edition, like its predecessors, will well serve the purpose of students anxious to obtain information which otherwise could be got only by a laborious search of the literature. It should be studied by all who aim at keeping abreast of modern developments in physiology.

Gonococcal Infection in the Male.

Second edition. By A. L. WOLBARST, M.D., Urologist, Beth Israel Hospital, New York. London: Henry Kimpton. 1930. Pp. 297. 25*s*.

THIS useful manual first appeared in 1927, and in the present edition the author has successfully resisted the temptation to enlarge the subject matter, the increase of 60 pages being mainly due to additional illustrations. The methods of treatment described do not materially differ from those in use in this country. It will be noted, however, that Dr. Wolbarst is one of those urologists, not few in number, opposed to the Janet irrigation treatment, which has, possibly unfortunately, now almost become standardised in this country. Instead he is an eloquent advocate of the old-fashioned urethral syringe, but with the important proviso that this must be handled by the physician, not the patient. For posterior irrigation, similarly, he recommends the use of a large bladder syringe, somewhat similar to the Thomson-Walker type used in this country. In the matter of drugs, the author is an advocate of the chemotherapeutic treatment of McDonagh, and in diathermy he follows closely the teaching of Cumberbatch and Robinson. It is interesting to note that he too has found diathermy, as at present applied, quite useless in the treatment of acute anterior urethritis in the male. The section on sterility in the male has been expanded, and the text generally has been revised, giving a sane, balanced, up-to-date picture of present-day treatment.

Symptoms of Visceral Disease.

Fourth edition. By FRANCIS MARION POTTENGER, A.M., M.D., Medical Director, Pottenger Sanatorium for Diseases of the Lungs and Throat, Monrovia, California. London: Henry Kimpton. 1930. Pp. 426. 31*s*. 6*d*.

IN this edition some additions have been made and a new chapter is included on the pharmacological and clinical tests "for sympathicotonia and parasympathicotonia." This chapter is in fact merely a cursory account of a number of tests with little criticism of their practical value, and insufficient detail to enable the reader to employ them. In other respects the book maintains its former scope, and is a real attempt to interpret symptoms of disease in terms of reflex nervous action. As a study of our recent physiological knowledge applied to clinical medicine it deserves to be read. The conception of sympathetic and parasympathetic reflexes of secretory, motor, sensory, and trophic types and their relation to diseased conditions may not be familiar to all clinicians; Dr. Pottenger gives a full description of this conception with some admirable illustrations and numerous references to larger works in the first part of this book. An appreciation of the importance of the vegetative nervous system and the endocrine glands is even more vital to the study of general medicine. The second part of the book is taken up

with a general review of the relationship between the vegetative nervous system and the symptoms of visceral disease, and the third part with the study of individual organs and their important "viscerogenic" reflexes. Clinical applications of these reflexes are given, and the author shows how disease of one viscus may reflexly lead to marked alteration in function of other and distant viscera. Dr. Pottenger's book will give, perhaps, a new point of view to some, and to others will offer explanation of a diversity of symptoms. For these reasons it may be recommended, though some of the views expressed are open to criticism. The printing and illustrations are excellent.

X Rays.

By B. L. WORSNOP, B.Sc., Ph.D., Lecturer in Physics, King's College, London. London: Methuen and Co., Ltd. 1930. Pp. 101. 2*s*. 6*d*.

THIS book on X rays is by the general editor of Methuen's recent Monographs on Physical Subjects. This series will commend itself to a wide circle of readers, who must, however, be prepared to obtain some knowledge of the subjects before attempting to read the monographs. Mr. Worsnop has tried within the compass of 100 pages to give an account of the developments in the science of X rays since their discovery. The reader is certainly given the essence of the subject, and if he does not find as many details as he would wish, he will remember what the author has clearly stated in his preface, that the book is only an outline. The references throughout the book are to individual pieces of research work which have been real sign-posts on the main road of discovery. Among the few flaws are the diagrams, some of which are so small that a magnifying glass is necessary to decipher them. The author expresses the hope that medical radiologists may find a use for the book. We feel sure that they will, but they must not expect to find it easy reading.

MENTAL HEALTH IN SCOTLAND.

THE sixteenth annual report of the General Board of Control for Scotland [1] opens on the modern and important subject of occupational therapy. Although it has long been the custom to set patients to work, they were often employed in the past more to keep them out of mischief and to reduce their cost of maintenance than for their personal benefit. Treatment by work in the modern sense appeared early in Scotland, for the Brabazon Society's voluntary workers demonstrated the value of handwork long before paid instructors were appointed. There is perhaps a tendency to over-rate the importance of the new "arts and crafts" idea of occupational therapy and to forget the real value of work in farm, garden, and house. This, after all, is the kind of work to which most patients in public hospitals have been born and trained and much of it has the advantage of providing physical exercise in the open air for patients of both sexes. The Board therefore encourages institutions to acquire and work land, and the advantages of this measure—primarily intended as a form of mental treatment—include a more varied and healthier dietary for all the inmates, a financial profit, and a more tranquil life for the restless and energetic patients and all who come into contact with them. The Board suggests further that some small remuneration should be made to recoverable patients, because this provides at the same time the necessary incentive to labour and some hope for the future, since they leave the hospital with a little money in hand.

PATHOLOGICAL WORK.

An interesting innovation is the establishment of a special department for carriers of enteric and similar fevers. Segregation of these people is of the utmost importance to the asylum population, not to mention the peace of mind of the staff. One of the Glasgow asylums, having to investigate an outbreak of contagious abortion in its herds, tested 112 consumers of the infected milk and other persons in contact with the cows. Ten men reacted positively to tests both for *Brucella abortus* and *B. melitensis*; nine of them lived in the farm colony and four worked in the byres. All were in good health, but when their histories were investigated carefully they were found to have had recurrent mild febrile attacks. Undulant fever is, therefore, endemic in this hospital.

The report notes with regret a decrease in research in institutions since withdrawal of the Government grant; small as this grant was, it seemed to provide a stimulus. The Medical Research Council and other trusts have, however, contributed to the work of the Scottish Asylums' Pathological Scheme, and the financial condition of the laboratory at Edinburgh is satisfactory.[2] During the year 192 specimens from nine hospitals were investigated in this laboratory, and the usual undergraduate and post-graduate teaching courses were held. The pathologist has published work on infection of the brain from septic foci in its neighbourhood. Other research has dealt with gliosis, the relationship of the lymphatic system of the peripheral nerves to the central nervous system, and the degeneration and regeneration of peripheral nerves.

THE FIGURES FOR 1929.

On Jan. 1st of this year there were 19,059 insane persons under the cognisance of the Scottish Board, an increase of 28 during the year. The total number of patients admitted during the year was 3173, a decrease of 136 on the previous year, but only one less than the average for the quinquennium 1925–29; of these, 800 were voluntary patients, of whom there were 950 in residence on Jan. 1st, 1930. The death-rate was 9·2 per cent. During the year 158 private and 969 pauper patients were discharged recovered. The Board's report does not reprint the reports of the visiting commissioners on each institution, but provides instead a brief account based on these reports. In Scotland, considerable interest is taken in the boarding-out system, and patients in crofts and small farms are exceptionally well fed and cared for.

There were 3074 mental defectives under care at the end of last year, two-thirds of them in institutions. The inmates are taught handicrafts and kept employed; there are, however, no farm colonies.

The Board has had under consideration the conditions of service of the nursing staff, for there has been some movement towards the establishment of an eight-hour day. The Board does not feel, however, that mental nursing is a profession lending itself to a rigid limitation of working hours and prefers to press for general improvements, such as the provision of nurses' homes and married quarters and an adequate supply of staff to allow for leave and recreation.

ON KEEPING AN EVEN WARMTH.

THE heat regulation of warm-blooded animals represents a biological mechanism of extraordinary subtlety and efficiency. A physicist would probably be surprised to see a small glass vessel, containing (say) 20 g. of water, exposed to variations of 30° C. or more and yet maintaining its temperature constant within one or two degrees. But this is what a mouse does unfailingly. The small mass of living cells represented by the body of a mouse not only generates enough heat to maintain the temperature if necessary 20 or more degrees above that of the environment, but it also keeps that temperature constant within very narrow variations, although the covering of the body consists of a very thin skin with little adipose tissue. As it is obviously a much easier problem to maintain at a constant temperature a huge tank containing many hundredweights of water, so the maintenance of a constant temperature in large animals, such as the horse, the cow, or the elephant, strikes one less by its efficiency. Even the heat regulation of the human organism, which for this purpose one may regard as a tank containing from 60 to 70 litres of water, seems an easy task compared with that successfully accomplished by a mouse. In his Croonian lectures, the publication of which is completed in our present issue, Sir CHARLES MARTIN has given a brief but masterly survey of the general plan on which this mechanism is built. He ends up by an enthusiastic declaration in favour of dress reform, the application of which, however, he wisely restricts to tropical climates. If we could imagine a man and a mouse crossing London Bridge on a gusty March day, both dependent entirely on the resources for keeping an even warmth with which Nature has endowed them, man would cut but a poor figure. It may indeed be doubted whether the human organism in its present state can accomplish the task of heat regulation without the aid of clothing and fire. At any rate we know that clothing and fire are among the earliest inventions of man, and were used by man even in palæolithic times. Most of us are familiar with the depressing effect of exposure to cold, when inadequately clad. The whole organism then concentrates its efforts on the task of "keeping an even warmth," and if this continues for any length of time a mental degradation sets in which goes even deeper than that produced by hunger. It is perhaps not too fanciful to associate the mental development of man with his invention of fire and of clothes, which freed him from the necessity of struggling against his thermal environment. It might even now be an interesting task for psychologists to see whether any relationship exists between mental activity and the thermal environment, both internal and external.

Enough has been said to show that the mechanism of heat regulation is one of very great complexity. Sir CHARLES MARTIN in his lecture has naturally laid most stress on the nervous mechanism, since that is the one which is most susceptible to experimental investigation and which has been very fully worked out. It is significant that Sir CHARLES finds it necessary to split the heat-regulating "centre" into three "centres." A logical purist might perhaps boggle at the notion and ask at what stage of this process of decentralisation a "centre" ceases to be a "centre," especially when in each case the centre is postulated to preside over a great many different functional systems: skin, circulation, respiration, metabolism. The conception becomes clearer if it is realised that, as Dr. W. CRAMER has pointed out, heat regulation is essentially the function of the sympathetic system including the thyroid and adrenal glands—a conception which has been confirmed recently by the work of CANNON, HASAMA, and others.

The mechanism of heat regulation is not the same in all mammals. In some species the activity of the sweat glands plays an important part, in others sweat glands are practically absent. Animals which regulate with the help of sweat glands are better able to withstand high temperatures, and this raises the interesting question whether the difference represents an adaptation to changes in climatic condition or whether it can be taken as indicating that these two different groups of species had their origin under different climatic conditions. To the clinician the pathology of the mechanism of heat regulation is of special interest. It is curious to reflect that, although fever is perhaps the commonest pathological phenomenon, it is still largely an unknown territory. Fever is the Cinderella of physiology and pathology—and also of pharmacology. For while antipyretics are among the drugs most commonly prescribed, our knowledge of their mode of action is even more defective than that of the condition which they are intended to relieve. Sir CHARLES MARTIN in his lectures quotes a statement by ISENSCHMID that the organism for the purpose of heat regulation has a whole orchestra to play upon, and he refers to the comparatively recent discovery that even the endocrine organs represent a hitherto unrecognised group of instruments. If this is true it also follows that these instruments can be called into action by changes in the external thermal environment, and by those conditions which manifest themselves by changes in the internal thermal environment—i.e., fever. Such a conclusion has extensive clinical implications. But clinicians and pathologists have been slow to take advantage of this new conception. In his recent Lettsomian lectures on the relationship of dermatology to other branches of medicine,[1] Dr. H. W. BARBER has shown how it can be used to correlate certain clinical manifestations, and there can be little doubt that similar progress will follow its application to other problems of clinical medicine.

[1] THE LANCET, 1929, ii., 363.

MEDICAL TREATMENT OF CONGENITAL PYLORIC STENOSIS.

IT has come to be the accepted practice in this country, at any rate in hospitals, for nearly all cases of congenital pyloric stenosis to be operated upon. As a result of good team-work the mortality-rate has been slowly reduced so that Dr. F. J. POYNTON, for example, in a recent report [1] was able to describe an 80 per cent. recovery in a series of cases. Despite this success most physicians dealing with these infants have not felt convinced of the absolute necessity for surgical intervention, and recent continental work with thickened feeds has been watched with interest. One difficulty about accepting the conclusions of the German school has been that under the title of "pylorospasmus" have been included cases in which the certain diagnosis of pyloric stenosis (by palpation of a pyloric tumour) has not been made and in general too little information about the clinical condition of the infants has been supplied. A recent paper by Dr. S. WOLFF, of Eisenach,[2] however, meets these objections and his spectacular results with medical treatment deserve close study. He is a sturdy opponent of the surgeons in this matter and his experience is a wide one. From 1912 to 1930 some 98 cases of congenital pyloric stenosis were under his care, and he lays down the cardinal points in diagnosis as vomiting, constipation, visible gastric peristalsis, and the presence of a pyloric tumour. All these cases were treated by him personally, the necessary procedures being carried out either by himself or under his direct supervision. The diet he now gives to these infants consists of frequent small feeds of thickened protein milk with added sugar, although formerly he used to prefer breast milk. Subcutaneous salines are injected at the onset in severe cases and stomach wash-outs begin the treatment in all cases. Atropine in the form of the valerianate is given by the mouth in drop doses with each feed; Dr. WOLFF believes that this preparation is the most useful because the sedative effect of the valerian counteracts any tendency of the atropine to excite the central nervous system.

The 98 cases treated during the 18-year period comprise 58 boys and 40 girls; it is an interesting fact, commented upon by other observers, that the majority of cases occurred in the first half of any year. Six only of the patients were operated upon and of the 92 cases medically treated only two died, giving a recovery-rate far superior to anything yet produced by surgical methods. An interesting feature of Dr. WOLFF'S series is the large number—80 out of the total 98—treated as out-patients. He classifies his cases under the four headings of mild, moderately severe, severe, and very severe, and in a comprehensive table sets out full details about the weight and progress of each child, including a note whether in his view the infants would have stood an operation. Many of the cases described suffered from complications which would have added greatly to the risk of any surgical procedure. Dr. WOLFF points out that while plastic operations on the pylorus do certainly relieve spasm at that site, spasms at other situations in the alimentary canal, which are not uncommon in these cases, are not benefited by such operations. This view will be new to most observers in this country, but it may explain some of those cases where vomiting continues after Rammstedt's operation in an unexplained manner. Dr. WOLFF quotes, with disapproval, a dictum from a surgical publication that "better one child too many operated upon than one child too few." While this may hold, he says, for acute appendicitis, the position is quite different when the physician is dealing with an infant only a few weeks old. He hints, also, that the widespread increase in the number of cases of pyloric stenosis occurring in hospital records during the last few years is directly due to too much surgical interest in the condition. While this may be dismissed as a provocative statement when it is included in a paper with a frankly anti-surgical bias, it should nevertheless stimulate physicians to consider whether the present line of treatment by Rammstedt's operation is the best which medicine has to offer for a malady where spontaneous cure is known to occur after the third month of life.

TREATMENT OF TRAUMATIC EPILEPSY.

NEUROLOGISTS have been aware for some time of the important investigations into traumatic epilepsy which have been conducted by Prof. OTFRIED FOERSTER of Breslau, and which have led him to develop a surgical technique for the treatment of selected cases. The physiological basis of this method of treatment is set out in two recent papers [1] [2] by Prof. FOERSTER and Prof. WILDER PENFIELD, of Montreal, which will repay study by all who are interested either in epilepsy or in the surgery of the nervous system. A happy union of FOERSTER'S study of excitable cortical areas and PENFIELD'S investigations of the behaviour of scar tissue in the nervous system has produced fruitful results. Not only has their collaboration suggested a plausible explanation for at least some forms of traumatic epilepsy, but it has also, if we accept the explanation, provided a rational basis for surgical treatment. FOERSTER, by electrical stimulation of the cerebral cortex in over one hundred patients under local anæsthesia, has outlined certain definite epileptogenic cortical areas which extend considerably beyond the "motor cortex" so called. In fact, such excitable areas are to be found in front of, and also behind, the precentral convolution as well as in the temporal and occipital lobes. The movement patterns which follow the stimulation of such areas provide a local sign which often makes it possible to localise the cortical focus of an epileptic discharge. These patterns are described in detail by FOERSTER and PENFIELD. The latter's

[1] Foerster, O., and Penfield, W. G.: Brain, 1930, liii., 99.
[2] Penfield, W. G.: Canad. Med. Assoc. Jour., August, 1930, p. 189.

researches into the process of scarring which follows experimental injury of the brain have shown that widely different reactions occur according to whether or not the damaged cerebral tissue is removed. If it remains, a scar containing connective tissue and fibrous astrocytes is rapidly formed and becomes densely attached to the overlying meninges and invaded by a rich plexus of newly formed blood-vessels. The scar contracts steadily for a period of years, and this contraction is responsible for the displacement of the cerebral ventricles towards the lesion which FOERSTER has demonstrated by encephalography. It is suggested by FOERSTER and PENFIELD that such scars are responsible for the occurrence of traumatic epilepsy, possibly by means of vasomotor changes reflexly induced by changes of tension. Surgical excision of such scars, if the bone-flap is not replaced, is followed by a more favourable type of gliosis which does not exert a similar traction upon the cerebral tissues. This is held to be the explanation of the beneficial results of such operations following which patients, formerly epileptic, have been free from fits for a number of years.

FOERSTER and PENFIELD'S work suggests reflections of both theoretical and practical interest. SARGENT reported that among 18,000 cases of gunshot wounds of the head, 800, or 4½ per cent., developed secondary epilepsy. This incidence has been interpreted as evidence in favour of some underlying predisposition to convulsions which is present in only a small proportion of individuals, and which is assumed to be necessary if cerebral trauma is to give rise to epilepsy. PENFIELD, however, suggests on the basis of W. W. WAGSTAFFE'S work that variations in the severity of the injury, especially whether or not the dura is penetrated, are an important factor in the production of this sequel. Nevertheless, even in traumatic epilepsy there is sometimes clear evidence of predisposition in the family history. It would be interesting also to know whether FOERSTER and PENFIELD'S observations throw any light upon the difference between the various clinical forms of focal epilepsy. At one extreme is the slow march of the Jacksonian attack; at the other the brief focal onset of a generalised fit, while epilepsia partialis continua remains a localised convulsion. Further, traumatic epilepsy which first manifests itself in the Jacksonian form may in course of time develop into fits which are generalised from the onset of the attack.

This work puts traumatic epilepsy in a new light and it is reasonable that operative treatment should be considered in such cases. Whether it should be carried out in a given case will depend upon several factors, especially whether the pattern of the fit or the presence of physical signs indicates the epileptogenic focus, whether encephalography provides evidence of a scar, and, perhaps most important, whether a surgeon with experience of the technique is available. Physiologically it is doubtful whether there is any reason for separating traumatic from other forms of epilepsy, for in many so-called "idiopathic" cases there is as good evidence for the focal origin of the fit. A better understanding of traumatic epilepsy, therefore, cannot fail to enlighten us upon the pathogenesis of convulsions in general.

ANNOTATIONS

THE PATIENT AS A WHOLE.

NOWADAYS it is widely taught that the patient must be regarded as a whole and not as an example in nosology. But there is still occasion for Dr. F. G. Crookshank's trenchant attack on what he calls "the organic school," or "school of mortuary medicine," and the "neuro-humoral school, who detest taking cognisance of what they call the subjective no less heartily than do the mortuary doctors refuse to admit the importance of the merely functional." [1] He urges the need for a comprehensive view of the individual, who is ill because he has "lost whole-th." It is, he thinks, a relic of mediæval demonology to say that we are "attacked" by disease, and the apparent support given to this attitude by bacteriology has been weakened by increasing recognition of the importance of the factor of resistance. Dr. Crookshank would no more allow us to suffer from "an attack of neurasthenia" —or presumably typhoid or influenza—than "an attack of adultery." He is an ardent apostle of the truth that, to study and diagnose any case completely, the doctor must consider the patient physically as carefully as any member of the organic school could wish; physiologically, in the spirit of the neuro-humoral school; and—neither more nor less important —psychologically. It is not necessary to say that he has a soul, but he has consciousness and memories—conscious, subconscious, and unconscious. Unless the physician takes stock of these, he is not taking stock of the individual. Every illness has its psychological aspect, and the good clinician faced with a patient who complains of vomiting ought not, in his absorption either in the digestive prescription, the test-meal or the areas of hyperalgesia, to forget also to ask—in an appropriate manner—"What are you sick of?" Dr. Crookshank takes his stand on the work of Alfred Adler and his followers, and finds in this school the most satisfactory marriage between psychology and clinical medicine. Adler's principles, put briefly, are that some inferiority or inadequacy in a bodily organ will account for disease, especially functional disease, without the intervention of any extrinsic factor, and that neuroses and psychoses commonly develop in association with organ-inferiorities. An organ which, because of some morphological or functional inferiority, is the weakest link in the chain, is more likely than others to break down under stress, but this congenital or acquired inferiority may be expressed in successful compensation, or in over-compensation, which itself causes distress. Or the purely psychological sense of inferiority, which is the heritage of everyone, may attach itself, if not overcome by suitable training and by personal courage, to the organ which suffers from some defect, and so establish a "functional" disorder. "Every neurosis," Dr. Crookshank says,

[1] Individual Psychology and General Medicine. F. G. Crookshank, F.R.C.P. Psyche, Cambridge, 1930, pp. 27, 1s.

" can be understood as an attempt to free oneself from a feeling of inferiority in order to gain a feeling of superiority."

CANCER RESEARCH IN AUSTRALIA.

THE difficulties of obtaining accurate and uniform records of treatment and results in cases of cancer are particularly great in Australia, where a relatively small population is scattered over a continent; but the establishment of consultative groups, consisting of physicians, surgeons, radiologists, and pathologists, has been adopted at the centres where radium is in use, and returns of cases have been analysed by Dr. Arthur Burrows, who has been acting as radium and cancer adviser to the Commonwealth Government. To what extent it is permissible to draw deductions from these returns has been recently discussed by Dr. Burrows in our own columns [1] when he announced the imminent appearance of an official report of the conference of Australian Cancer Organisations, held at Canberra, in April last. This report, a copy [2] of which has now reached us, while it does not add materially to our knowledge of cancer, contains observations of more than passing interest. In Queensland, we learn, lead therapy has been discontinued as the result of an unfavourable report by Dr. L. M. McKillop, of Brisbane, after investigation which included visits to Liverpool, London, and certain American cancer clinics. Dr. W. J. Penfold, of Melbourne, discussing some of the possible avenues of research, suggested that it would be valuable to discover whether there were any individuals in whom the general resistance of the tissues to lead was greater than that of the local growth; it would also be of service to be able to detect those who were supersensitive to the action of lead. Radium and X ray therapy have received careful study. Dr. E. H. Molesworth, of Sydney, advocated a close watch on the pathological characteristics of every tumour in order to choose for each patient the treatment offering the best chance of life. He is opposed to the belief that a shorter wave-length has a selective action on malignant cells; owing to the localised character of the intense effect of embedded radium it is, he believes, possible to deliver to the growth, without danger, a dose double the size of the X ray erythema dose. Although it would be possible to achieve the same dose, say in the uterus, by means of the deep X rays, the effect would be much more widely distributed and would involve bowels and bladder; the advantage of radium, he considers, lies not in the penetrating properties of its rays, but, on the contrary, in the rapidity with which the intensity of its radiation fades as it leaves the source of origin. He offers this as an argument against the use of the radium bomb where deep X rays can produce the same effect; not only is it less expensive to use X rays than a radium bomb at a distance of 20 or even 10 c.cm. from the skin, but the danger to attendants and operators is eliminated almost entirely. Both methods have the same limitations of dose as registered by the skin reaction, and the only advantage he finds in the radium bomb is that the dose may be delivered continuously over a period of days, instead of intermittently as with deep X rays. X rays can do as much as radium at a distance in supplementing implantation, and the measurements of dosage are more accurate and better expressed.

An observation deserving remark has been made by Dr. McKillop, who finds that precancerous conditions of the skin appear to be very common in Queensland, and an investigation has been undertaken by Dr. J. V. Duhig, to decide the importance of sunlight as a factor in the genesis of cancer of the skin.[3] Apparently, hyperplasia with a malignant tendency is so common in Australia that clinical diagnosis is quite unreliable. In hyperkeratosis the best results have been obtained with carbon dioxide snow, and with definitely malignant lesions radium in the form of a plate has been employed with some success. The use of other methods has not meant the neglect of surgery, and the value of the endotherm knife of Wyeth—the electric scalpel—is strongly advocated by Dr. A. J. Cahill, of Canberra. The absence of much tissue manipulation, the sterilisation of the field by the knife, and the rapidity of healing are among the advantages his experience has led him to expect; in addition, hæmorrhage is lessened, and owing to the destruction of sensory nerves, pain is much reduced. He observes, however, that the use of this instrument cannot be learned completely during a short experience; it calls for judgment and discrimination in its application, and for increasing boldness with a growing technique.

TREATMENT OF SECONDARY ANÆMIA.

STIMULATED by the success of liver feeding in pernicious anæmia, many workers have tried this form of therapy in cases of secondary anæmia; but, although reports are conflicting the main consensus of opinion seems to be that it is of little value. Giffin and Watkins [4] have lately studied the effect of desiccated fœtal liver in obscure secondary anæmia. The liver was obtained from fœtal calves at the age when the blood-forming islands of the liver parenchyma show their greatest activity. The investigators find that about 80 per cent. of 102 cases which received adequate doses showed well-marked improvement. Thirty-five cases in which both iron and adult liver had previously been administered with no effect responded to treatment with desiccated fœtal liver. Although it may be necessary to persevere with the treatment for as long as two months before there is any improvement, once this improvement has begun it seems to persist, even if treatment is discontinued. One reason for inconsistency of results in the treatment of secondary anæmia is probably the number of different conditions which receive this diagnosis. On careful examination many patients with chronic secondary anæmia are found to harbour some chronic focus of infection, or to have small chronic hæmorrhages from a lesion of the alimentary tract. In cases of post-hæmorrhagic anæmias which exhibit delayed blood regeneration, Dyke [5] has found that liver therapy is attended with marked improvement. Recently, Witts [6] has called attention to a group of cases which he calls "simple achlorhydric anæmia." Although the condition has been described before, it does not seem to be generally recognised in this country, and is mentioned in none of the standard text-books on diseases of the blood. The syndrome, he says, appears to be closely related to pernicious anæmia, but the blood picture never shows any megalocytosis. It is far more common in women than in men, and achlorhydria is the rule. The spleen may be palpable, there is frequently

glossitis, and nervous symptoms, such as acro-paræsthesiæ, may occur, but it is doubtful if there is ever true subacute combined degeneration of the cord. No evidence of blood destruction is observed, the van den Bergh reaction being negative. Another curious sign sometimes seen is that the finger-nails, instead of being convex, as normally, may be concave or spoon-shaped. Although achlorhydria is apparently the main ætiological factor, since it is present before the anæmia develops and persists after its cure, administration of hydrochloric acid is entirely valueless, as also is liver feeding. However, marked improvement of the anæmia and general health, including the finger-nails, follows the exhibition of iron in large doses (two or three times the pharmacopœial dose). Witts thinks the condition is closely allied to the Plummer Vinson syndrome of dysphagia with anæmia. These observations are useful as indicating the lines along which clinical research must progress before "secondary anæmia" ceases to be considered a diagnosis, and takes its proper place as a symptom.

MYOPIA IN SCHOOLS

A REPORT by Mr. C. L. Gimblett[1] deals with refractive changes in the eyes of 170 children from the East Ham Council Schools, observed by him for varying periods during the six years from 1923 to 1929. All these children showed either some degree of myopia in one or both eyes, or an astigmatism in which either one or both meridia were myopic, this being found at the latest—not necessarily at the first—examination. The conclusion of the author is that in the East Ham schools the average rate of progression of myopia during school life is 0·4 dioptre per eye per year—that is to say, a child entering school at the age of 5, with normal sight but with a tendency to myopia, progressing at this rate for ten years, would leave school at 15 with a myopia of 4·0 D. Comparing the different schools it is found that in certain schools the incidence of myopia is far higher than in others, so that the schools can be arranged in order according to their "myopic index"—i.e., the figure representing the relative number of myopic pupils. Correlating this with the different factors likely to affect myopia, it is found that where competition for scholarships is keenest, as in the secondary school, there myopia is most frequent. On the other hand, the rate of growth of myopia is not so high in these schools as in some of the smaller ones where competition is not so keen. No explanation of this is suggested. No evidence was found that bad lighting had any unfavourable effect on either the incidence or the progress of myopia. The influence of heredity was shown in a large proportion of myopes, and in families free from myopia there was evidence that the onset of myopia was often preceded by one of the common infectious diseases. Of the children examined, 101 were girls and 69 boys. The greater number of them —78 per cent.—were first found to be defective during the middle period of school life, between 8 and 12, and the periodic examinations revealed that the myopia progressed most rapidly during this period.

The great majority of the cases with which this report is concerned are those of ordinary school myopia, with no fundus change beyond the ordinary "myopic crescent." A few high myopes are included in the list, and it is an unsolved problem in the case of highly myopic children how far the condition is due to a congenital malformation and how far to a stretching of the sclerotic coat after birth. According to Mr. Gimblett, congenital myopia is a distinct entity, and does not tend to become worse as the result of the stresses and strains of childhood and adolescence, but beyond citing a few cases in which myopia of moderate degree remained stationary during school life, he gives no sufficient evidence to support his view. In any case there will be general assent to his recommendation for the treatment of the East Ham myopic children, which are on lines generally adopted by progressive education authorities elsewhere. Three types of modified education are available. (1) *Easy treatment.* At school the pupil is allowed to sit in front and to read large print for not more than a quarter or half an hour at a time. Homework is curtailed, and girls are not allowed to sew, but may knit. Special attention is to be paid to the "stance" (sitting up). This treatment was prescribed for any myopic pupil if, after a few months, the myopia was progressive. (2) *Oral teaching only* is prescribed when "easy treatment" fails to arrest the progress of myopia, or when it is not practicable for the pupil to be taught in a special myope class. Books and writing materials are prohibited both at home and at school, and unless the procedure is to be a farce, the coöperation of parents at home is essential. Writing in the free-arm manner on blackboard or paper in characters not less than two inches high is allowed. Oral lessons are attended. No gymnasium or dumb-bell exercises are permitted; exercises with bending and stretching are supposed to be bad for myopia, on the theory that any congestion of the head and eyes favours its increase. (3) Lastly, there is the myopes' *sight-saving school*, reserved for specially bad cases and organised on the lines laid down by Mr. Bishop Harman, in which "oral teaching only" is more systematically carried out than is generally practicable in the ordinary school,.

A certain number of these children—8 out of 170—were found to have a divergent squint before the age of 15, due to fatigue of the converging muscles and of the coördinating mechanism by which they are governed, and this constitutes a further argument in favour of the precautions recommended.

EUGENIC REFORM.

ADDRESSING the International Federation of Eugenic Organisations on Sept. 12th, Mr. C. J. Bond said that medical inspection of 6,000,000 children in 1928 showed that 1,000,000 were so defective, physically or mentally, as to be unable to derive reasonable benefit from the education provided by the State. He added that in the opinion of experts a considerable proportion of this unfitness is the outcome of inherited tendency. At the same meeting Sir Arthur Keith discussed the changes produced by civilisation which have made natural evolution unsatisfactory as the controller of our destinies. At present, humanity is a mere pawn in the game, but it is high time for it to take a hand. The possibility of eugenic reform depends, in Sir Arthur's opinion, on the extent to which human nature can be rationalised and the times are now more favourable than ever before; for increase of population is forcing public attention to the subject. All human communities being unstable, the aim of eugenists is to control the direction of their changes to the advantage of the race. They will find allies in the many men and women nowadays interested in the laws of human heredity, but eugenics has a

formidable antagonist in the instinctive obedience of mankind to the demands of Nature for reproduction—of whatever quality. Unfortunately or fortunately, human beings are ruled less by reason than by passion, emotion, prejudice, and instinct, and Sir Arthur gives no indication of the time which will be necessary to breed out these characteristics.

COLONIES FOR MENTAL DEFECTIVES.

AT the opening of the new Coleshill Colony near Birmingham last week, Mr. L. G. Brock, chairman of the Board of Control, made some remarks on the care of mental defectives in this country. A third of the defective population, or something like 100,000 individuals, were, he said, unfit to be left at large in the community and required institutional treatment. Most poor-law buildings could hardly be regarded as suitable for housing any except the lower grades of defect. A well-organised colony provided opportunities for the higher-grade mental cripples to live a useful life. The Birmingham scheme includes the erection in the 180-acre park of a number of villa annexes, a workshop, and a recreation room, at a total cost of about £89,000. Mrs. E. F. Pinsent, a commissioner of the Board, who was also present at the opening ceremony, thought it might be possible to reduce, to some extent, the numbers needing colony care by the establishment of day occupation and industrial centres, as had been done in Leeds and Bristol, and by setting up hostels where a small proportion of feeble-minded girls and boys could be trained under conditions freer than in the main colony, going out on licence to suitable and carefully chosen situations.

It is an ironical commentary on our statesmanship that 16 years after the Mental Deficiency Act was passed to make proper provision for defectives the great majority are still being cared for, not by the mental deficiency committees of local authorities, but by bodies set up for an entirely different purpose. When, therefore, the county councils took over their new duties in April last, they must have found a large number of mental defectives over and above those ascertained by their own committees. Even under the new Act, defectives under the poor-law will still receive help for some years through the public assistance committee. That all of them may soon be brought under one governing committee is the earnest hope of Dr. F. D. Turner, expressed in the seventy-first annual report of the Royal Eastern Counties' Institution for the Mentally Defective. In a valuable summary of the history of this institution, which was founded in 1848 and first known as "The Asylum for Idiots," Dr. Turner discusses the new duties of the county councils, and points out the unsuitability of the ordinary type of workhouse for defectives, urging the colony as the essential solution. There are now 1300 inmates on the books of the Eastern Counties' Institution, grouped in nine houses; plans for a big extension have been passed and work is now proceeding. The most important event in 1929 was the taking over of Littleton House School, Cambridge, as a part of the institution; another new branch has been opened at the Retreat, Witham, while another farm has also been added, bringing the total acreage to 380. Improvements have been made in the various buildings, much of the work being done by the men and boys themselves. Unless consent is refused, all new admissions to the institution are Schick-tested, and the 61 who gave positive reactions received three doses of toxoid-antitoxin. Except for one boy who caught diphtheria before he was tested, there has been no case since the test was introduced in 1925; before that time small outbreaks occurred repeatedly. There has been a certain amount of mild sporadic dysentery and diarrhœa among the low-grade defective boys at East Hill. All the boys were given a course of antidysentery vaccine by mouth; there were no reactions, and no case has occurred since. The workshops have continued to turn out good work for which there is a satisfactory sale. The death-rate for the year was 1·85 per cent. The average death-rate from tuberculosis during the last three years has been only 0·6 per cent.; 15 cases were under treatment at the end of the year.

ENURESIS.

IN the report of the Kent school medical officer, summarised last week (p. 665), Dr. S. A. Tucker dealt with a matter that deserves more attention than it usually receives. He finds that more than 1 per cent. of school-children wet their beds at night, boys more than girls in the proportion of 7 to 5, that the habit tends to disappear with age, but that when it persists it gives rise to much distress and is a serious hindrance to education and employment. The causative factors of enuresis he groups under the five headings: (1) bad training; (2) physical defects, especially adenoids; (3) nervous causes; (4) nutritional (? absence of vitamin D); (5) thyroid deficiency. Treatment is directed to the removal of these causes, and may be hygienic, medicinal, or psychological. Hygienic measures include the restriction of stimulating diuretics such as tea, coffee, and spices, and of all fluids after 6 P.M., with the inculcation of the habit of micturition (and defæcation) just before going to bed. Removal of adenoids has effected a cure in several cases, and conditions like phimosis or hernia should be dealt with, although they have no direct relation to bed-wetting. Presumably adenoids are of importance in so far as they disturb sleep, while their removal is a starting-point for suggestive treatment. Highly acid or alkaline urine is probably so rarely an essential factor as scarcely to need mention. Belladonna, hyoscyamus, and bromide may help for a time, or may even sometimes effect a cure. Thyroid extract has had its successes, but also its drawbacks. Dr. Tucker does not specify the type of case for which thyroid treatment is appropriate, but here we may get some help from Dr. H. W. Barber's parallel observations on chilblains which are only benefited if hypothyroidism is present,[1] otherwise it is useless or worse. Iodine is regarded with approval by some; it may benefit a few special cases, but the evidence is not complete. As to psychological treatment, Dr. Tucker tells us that the one case treated by psycho-analysis failed completely, while a cure was effected in another child by suggestion of improvement with the prospect of a reward. He is against rebukes or methods liable to cause fear, for there is risk in allowing these nervous and sensitive children to get into a state of despondency; and he does not place the same value on positive suggestion as do others in this country, and especially in America where enuresis has been treated largely on the lines of any other disorder of conduct.[2] In the most recent American study,[3] however, it is admitted that "the data at our command

[1] THE LANCET, 1926, ii., 1180.
[2] THE LANCET, 1929, ii., 396.
[3] Diseases of the Genito-Urinary System in Infancy and Childhood. H. F. Helmholz and S. Amberg, Clinical Pediatrics, vol. xix., pp. 47–59.

seem to indicate that a psychic origin alone cannot be regarded as the only ætiologic factor." Dr. Tucker notes that several of his bed-wetters were of poor mental or social grade; the psychopathology of these cases differs from that of the majority, who tend to be intelligent, highly-strung children. Enuresis is not so common among the mentally defective—apart from the very low grades—as is generally supposed; those who have to deal with delinquents too, have found, somewhat to their surprise, that it is not specially frequent in this group. When the trouble occurs in high-grade defectives or subnormal children it often seems due to laziness and lack of sense of shame, a sharp contrast to the excessive shame and fear which occur in the neurotic. In the subnormal children there is likely, also, to have been a lack of training, and the line of treatment is persistent discipline in the sense of stimulus and training, not of punishment. The rationale is to anticipate the event by adopting, in addition to the usual régime, the following procedure. By inspecting the child's bed at intervals during the night, it is ascertained at what hour it is wetted—usually the time varies but little; the child is then wakened every night about half an hour before this time. The method, which calls for some self-sacrifice on the part of the attendant, has been highly successful, for instance at Besford Court Training School. It takes the place of the American method of an electric bell set in motion by the wetting, which has a less comic but more drastic development in a specialised apparatus which, in addition to ringing a bell, establishes contact with a faradic current sufficiently strong to wake the child. For other types of case methods such as these may do more harm than good; the vital point is to make sure to which type the case belongs and then to persist patiently with the appropriate treatment. This commonly means the elimination of local and physical causes and the faithful carrying out of domestic measures with the help of some simple form of psychotherapy.

TUBERCLE-FREE HERDS.

It is no good pretending that the maintenance of tubercle-free herds is easy. The Birmingham health report for 1929 shows that there are now 19 herds, comprising 663 animals, in the special scheme instituted in 1907 for eradicating tuberculosis from the city's milk-supply. Twelve of these are kept up by breeding and seven by both breeding and purchase. In the 12 breeding herds, comprising about 385 cows, 993 tests during the year resulted in 96 failures and four doubtful reactions. In the seven mixed herds, comprising about 278 cows, there were 34 failures and two doubtful reactions among 757 tests. Nine of the 19 herds are used for supplying Certified or Grade A (tuberculin-tested) milk to the city. Only three herds out of the 19, comprising 120, 49, and 7 cows respectively, had no reactors at the half-yearly testings of 1929. It was as long ago as 1894 that Bang described his scheme, subsequently adopted by the Danish Government, for the gradual eradication of bovine tuberculosis. His large experience had already proved that the calves even of tuberculous mothers were born healthy, and that tuberculin was almost infallible in diagnosis. The precautions proposed for reliable tests were then much as they are now, although the technique has been somewhat improved. In the progress of the Danish scheme unexpected difficulty was found in avoiding reinfection. Obviously this should be easier where a herd is maintained solely by breeding. Recently the tubercle-free herd kept by the Victoria Hospital Trust, Edinburgh, was infected by contact for a short period with a stray cow. Again, is the danger from porcine or other animal tuberculosis always guarded against adequately? The Dumfries county veterinary inspectors recommend double fencing, and also point out that a purchased cow may pass the test but be in the incubation stage, as the result of recent exposure to infection. In Scotland it is held that the use of pastures which have been grazed by infected stock has been a source of trouble. It might, perhaps, be well to have a pooling of experience or round-table conference of veterinary surgeons who have actually had experience of trying to keep herds free from tubercle—to be followed by an investigation of how other countries (such as the United States, Canada, and Denmark) are faring in this campaign. The island of Guernsey has tubercle-free cattle and a more or less normal death-rate from human tuberculosis. It would be interesting to know if the cows in Guernsey are ever accidentally infected from a human source. Such an investigation would be of world-wide interest, and might secure support from a body like the Rockefeller Foundation.

THE ORAL ADMINISTRATION OF A PRECIPITATE FROM CRUDE INSULIN.

From the biochemical department of the Carmichael Medical College, Calcutta, comes the latest attempt to find a preparation with the properties of insulin which can be administered by the mouth.[1] H. N. Mukhirjee, who had previously shown that the blood-sugar level is definitely depressed in rabbits (and also in diabetic patients) after oral administration of the precipitate obtained by treating commercial insulin with phosphotungstic acid, now claims to have produced typical hypoglycæmia with paralysis of limbs and convulsions by using the bulky precipitate obtained from crude insulin prepared in the laboratory, the insulin having been extracted from fresh beef pancreas according to the method described by Somogyi, Doisy, and Shaffer (1924). The precipitate of active substance is taken up in about 50 c.cm. water per kg. of pancreas, and an equal volume of 10 per cent. H_2SO_4 is added to it. After mixing by stirring, 30 per cent. solution of phosphotungstic acid in water is added in slight excess till no more precipitate forms. The precipitate is thoroughly stirred and is allowed to sediment in measuring cylinders. At the end of three or four days the precipitate per kg. pancreas is about 70 to 80 c.cm. in volume. On centrifugalising the volume is further reduced by about half, the clear supernatant fluid is discarded, and the precipitate is ready for oral administration. The substance is said to retain its potency well even after it has been kept at room temperature for several months. The material is treated with an equal volume of distilled water and is thoroughly mixed, 4 to 6 c.cm. of the mixture being given by mouth to rabbits fasting for 20 to 24 hours To diabetic patients fasting for 16 hours 10 c.cm. of the precipitate in 20 c.cm. of water have been given. The substance does not appear to have toxic effect when thus administered, and in many cases the effect on the blood-sugar level is said to be as marked as that of subcutaneous administration of insulin. Doubtless this preparation will be speedily tried out in laboratories. Previous attempts to supply a preparation of insulin or a substitute by the oral

[1] Journal of Physiology, 1930, lxx., 183

route have not been successful. Simple oral administration of insulin itself is completely without effect, and rectal injections are also useless. It is not certain upon exactly what factors the destruction or non-absorption of insulin from the stomach and intestine depends, though the reaction of the gut contents undoubtedly plays a part. Recently R. Stephan has recorded his observations and results upon this subject.[2] He considers that for the absorption of insulin by mouth there requires to be both an absence of ferments in the stomach and a regurgitation of bile into the stomach, and that absorption can only occur from the gastric mucous membrane. He found that a combination of insulin with bile acids was not destroyed in the fasting stomach, and was absorbed as rapidly as is the insulin hydrochloride from the skin. He thus gives an initial dose (2 g.) of magnesium sulphate to clear the stomach, and then a preparation of insulin-desoxycholic acid, of which 1 c.cm. is equivalent to 20 units of insulin. This preparation, which is named cholosulin, he found to be more active when previously exposed to the action of ultra-violet light and when food is taken after its administration. M. Ottow[3] also speaks optimistically of his results with cholosulin, but, as was noted in THE LANCET of May 24th, 1930 (p. 1139), others have not had such satisfactory experience with this drug. A. Bratusch-Marrian[4] records failure after its administration in three young diabetics, and attributes Stephan's favourable results to a spontaneous improvement in tolerance which almost every diabetic shows when taken into an institution with careful regulation of diet. We have thus still to find a preparation of insulin which can act by mouth in the way that this hormone acts parenterally, and the results of other workers with the phosphotungstate precipitate will be awaited with interest.

A NEW DIPLOMA IN GYNÆCOLOGY AND OBSTETRICS.

ANNOUNCEMENT has been made in our advertisement columns of a diploma in gynæcology and obstetrics to be awarded by the English Conjoint Board on the results of an examination to be held for the first time on Oct. 23rd. Any who intend to present themselves for this examination should inform the Secretary of the Examination Board now, as 21 days' notice is required. Candidates must have held for not less than three years a degree in medicine and surgery recognised by the Board or a qualification registrable in this country. The examination is written, oral, and clinical. Papers will be set on (*a*) gynæcology and obstetrics, including pathology, histology, and bacteriology; (*b*) antenatal, postnatal, and infant welfare work. Evidence is also required of having held a resident appointment in a gynæcological and obstetrical department or maternity hospital, and of responsible care of patients at antenatal, postnatal, and infant welfare clinics. These conditions may be modified at the discretion of the committee of management in the case of candidates who have carried out original investigations or who have had special opportunities of study, but exemption will not be granted from any part of the examination itself.

It may be recalled that the Royal College of Surgeons of England was empowered by its Charter of 1852 to appoint examiners for testing the fitness of persons to practise in midwifery and to grant licences of such fitness; but these examinations were discontinued in 1875. The Society of Apothecaries recently instituted a Mastery of Midwifery, denoting the possession of specialised knowledge of antenatal care, midwifery, and child welfare; and the University of Dublin (Trinity College) confers a diploma in gynæcology and obstetrics upon registered medical practitioners who have taken a special course at the Rotunda Hospital or other recognised institution, as well as a mastership in obstetric science which may be taken two years after the qualifying B.A.O. London University specifies midwifery and diseases of women as one of the branches for the award of its M.D. degree. The British College of Obstetrics and Gynæcology, founded last year, has power under its memorandum of association to grant diplomas, either alone or in coöperation with authorised teaching and examining bodies.

PROF. H. B. DIXON.

Harold Baily Dixon, who died last week, had occupied for 36 years the chair of chemistry at Owens College in succession to Sir Henry Roscoe, who had held it for the previous 30 years. Both made big contributions to chemical science and to educational work in Manchester; they must, too, have moulded in considerable degree the thought of successive generations of medical students. Roscoe set a high standard of lucid lecturing. Dixon lectured to students who were also listening to Milnes Marshall and Arthur Schuster, but no one who sat under Dixon will forget his unquenchable enthusiasm as a teacher; his lectures were permeated with the spirit of inquiry, and students were led to consider the methods by which results had been obtained and the arguments upon which theories were based. Dixon's research work was coloured by the character of the industries by which he was surrounded. Just fifty years ago he made the discovery that explosive mixtures of gases do not explode when sparked unless a trace of water vapour is present. This work not only foreshadowed the theory of chemical go-betweens or catalysts but led Dixon on to measure the explosion wave in different mixtures of gases, and so to approach some of the complicated problems of explosion in coal-mines. He became a commissioner of coal-supplies and a member of the executive committee on Explosions in Mines (1911–14). Dixon's interest in education did not end with the lecture room and the laboratory; it was his aim to see that Manchester boys and girls had systematic instruction in branches of knowledge which had direct bearing upon the leading industries of the city and district, and as he was chairman of governors of several groups of schools he was able to put his aim largely into effect. He had resigned the chair of chemistry in 1922 but had carried on research in the University laboratory until the time of his death.

Prof. John Beresford Leathes, F.R.S., will deliver the Harveian Oration of the Royal College of Physicians of London at 4 P.M. on Saturday, Oct. 18th.

UNIVERSITY COLLEGE HOSPITAL.—The annual dinner of past and present students will be held on Friday, Oct. 17th, at 7 for 7.30 P.M., at the Hotel Victoria, Northumberland-avenue, London, W.C., with Mr. Herbert Tilley in the chair. Tickets may be obtained from the dinner secretary at the Medical School, Gower-street.

MODERN TECHNIQUE IN TREATMENT

A Series of Special Articles, contributed by invitation.

CCCVIII.—TREATMENT OF BREECH PRESENTATIONS.*

BREECH presentations are found in the antenatal period very frequently up to about the thirty-fourth week. After this time they are much more uncommon, owing to the fact that spontaneous version to a vertex occurs in a large proportion of cases from the thirty-fourth to the thirty-fifth week of pregnancy. For this reason it is unnecessary to interfere in any way earlier than the thirty-fifth week. In a small number of patients the hard head in the fundus causes pain from the thirty-third to the thirty-fourth week, and if version is done the pain is relieved; in such cases it is worth while to turn the child early simply for the relief of pain. In about 3 per cent. of all labours there is a breech presentation. The fœtal mortality in breech cases is nearly 10 per cent., the figures at Queen Charlotte's Hospital being 11 per cent. in primigravidæ and 8 per cent. in multigravidæ. The disadvantages to the mother of a breech labour are the greater risk of exhaustion from a long labour and greater liability for lacerations to occur.

It is important that every patient should have as easy a labour as can reasonably be achieved for her; and, since the fœtal risk is so definitely increased in breech labour, it is much the best practice to turn all breech presentations into vertex presentations before the onset of labour. In a primigravida the most satisfactory method of ascertaining the relative size of the child and the pelvis is by pushing the head into the pelvis and thus gauging the proportions of the head and pelvis. For this it is essential that the presentation should be a vertex, and this is, therefore, an additional reason for converting a breech into a vertex presentation in the antenatal period.

The ideal time for doing version in a primigravida is about the thirty-fifth week of pregnancy. As a rule at this time the presenting part has not yet descended deeply into the pelvis and time has been allowed for spontaneous version to occur. It is often possible to do version easily without anæsthesia, and this practice has the advantage that it prevents the obstetrician from using undue force. An anæsthetic may be necessary where the patient is unduly nervous or where the presenting part is deeply engaged. In such cases version is usually delayed until about the thirty-seventh week, in case the manipulations and anæsthetic should combine to bring on labour. I have never seen an untoward complication following version in the antenatal period.

Technique of Version.

In doing version the first manœuvre is to push the breech out of the pelvic brim fully, then to pull the head downwards towards the other side of the abdomen. The direction of choice is to push the head round towards the pelvis away from the back of the child. By this means the flexion of the child will not be disturbed. When version fails by pushing in this direction, the other direction can be tried and often succeeds without harm ensuing. The Trendelenburg position is a useful preliminary to version where the presenting part is engaged. After version the head will often sink low into the pelvis; but if this does not occur a binder is applied and the patient is seen in a week's time. The use of a binder is particularly to be recommended after version in a multipara, where the abdominal wall is often weak, and, therefore, the breech presentation is liable to recur. In a multipara the version is generally done at a later date than in a primipara—generally about the thirty-seventh week. There is no harm in doing it earlier, but there is a greater tendency for the presentation to recur than in a primigravida.

Failure to effect version is often due to extension of the legs of the child, or to the fact that the breech is so deeply engaged in the pelvis that it is impossible to move it. After failure to turn has occurred in a primigravida it is instructive to have an X ray photograph taken in order to ascertain exactly the position of the child.

PRECAUTIONS IN DIAGNOSIS.

Great care is needed in antenatal palpation to avoid the mistake of diagnosing a vertex presentation when in reality an extended breech is present. In order to avoid this mistake, the following points must be remembered: (1) The presenting part feels smaller and is more conical than the head would be, and no sulcus can be felt (as between the head and the shoulders). (2) The head in the fundus feels harder than the breech would feel, and small parts are felt near it. (3) The whole uterus is narrower from side to side than in a vertex. (4) On vaginal examination the presenting part is softer than the head would be.

In spite of great care in examination it is very easy to make this mistake; if there is any doubt an X ray photograph will settle the diagnosis.

Where Version has Failed.

In conducting a labour where version has failed, it is advisable to keep the patient lying down in the first stage, since early rupture of the membranes is very liable to occur. The labour should be allowed to proceed naturally, and there should be no undue hurry. In the second stage the patient should be encouraged to bear down as much as possible. As soon as the breech is completely born, the legs are gently brought outside the vulva and the legs and breech wrapped in a warm sterile towel. It is very important not to pull on the legs at all. The part of the child which is born is held in the hands and the cord is pulled down a little, so that its pulsation can be observed. As soon as the edge of the ribs appears two fingers of the right hand are passed up the side of the child, to make out whether the arms are extended or not. It is advisable not to push on the fundus until the arms are born, as this is likely to cause extension of the arms.

If the elbows are felt easily, the arms are cautiously brought down, and when the next pain occurs the assistant pushes on the fundus, and the shoulders are born. The head then sinks into the pelvis. If this does not occur at once extra pressure is exerted on the fundus and will usually push the head into the pelvis. After the head is in the pelvis the child is turned, so that its back is upwards, and the child is then delivered by drawing the child's legs up over the patient's abdomen. Firm suprapubic pressure is used at the same time to aid delivery.

If the head is delayed it is necessary to extract it as quickly as possible. Occasionally the delay is due

* An article in this series by Miss Dearnley, on the Treatment of Posterior Positions of the Vertex, will appear in a future issue of THE LANCET.

to the fact that the dilatation of the cervix is not quite complete. If the cervix is felt over the forehead of the child, it should be pushed up at once, when the head will descend. If the head does not descend and no rim of cervix is felt, the child is pulled downwards and backwards, suprapubic pressure being kept up until the head descends into the pelvis. In other cases, where the delay is in the pelvic cavity, the child can be delivered by passing one hand along its chest until a finger can be put in its mouth; traction is then exerted in a forward direction—changing into an upward direction, whilst firm suprapubic pressure is exerted.

In some cases the following grip is most effective where the delay occurs at the brim. The left hand is passed under the child along the front of the chest—the second finger is put in the mouth and the first and third fingers on the clavicles. The right hand is placed along the back of the child, and the first and second fingers are placed over the shoulders. The child is drawn downwards and backwards—flexion of the head being promoted at the same time. The assistant at the same time makes firm fundal pressure. When the head has entered the pelvic cavity the back of the child is turned to the front and delivered as described previously.

It is the custom to have forceps boiled and ready for use in all cases of breech delivery, and in a small number of cases it is possible by this means to deliver the child alive where otherwise it would be dead. In applying forceps to the after-coming head it is of great importance to hold the child's body well up towards the mother's abdomen, so as to be able to apply the forceps correctly.

Breech Presentations with Extended Legs.

In a few cases in which the child is small and the pelvis normal, delivery of a child with legs extended is possible. Unfortunately this is not possible, and it is unwise to wait in the hope that it will prove so. Unless the labour is progressing unusually quickly, it is most dangerous to wait at all. It is generally held that as soon as dilatation of the cervix is practically complete an anæsthetic should be given, and that one or both legs should be brought down. If possible both legs should be brought down as this renders the subsequent delivery easier. No traction should be exerted on the legs or extension of the arms will result. As there is an additional risk of extension of the arms after any interference, an examination is made as soon as the costal margin of the child is born, and if the arms are found to be extended they should at once be brought down. The omission to do this is the most common reason for losing the child. If the arms are lying extended by the side of the head, or with the elbows flexed and the forearms in front of the face, it is best to bring down the posterior arm first, as there is more room in the hollow of the sacrum than in front. The hand is passed into the pelvis until the fingers lie along the forearm of the child. By pressing on the forearm the elbow is flexed, and the arm swept over the child's face. The anterior arm is brought down in a similar manner. In some cases where it is found impossible to reach the anterior arm, it is necessary to rotate the child so as to bring the arm posterior before bringing down. The rotation should be towards the side where the back lies, otherwise a dorsal displacement will occur. If a dorsal displacement of the arm is found, the child must be rotated towards the side where the back lies so as to rectify this to some extent, and then the arm is brought down manually as above. In some cases of extended breech in a primigravida, where there is difficulty in delivering owing to a tight perineum, a timely median episiotomy will be the means of saving the child.

In all cases of breech delivery it is common to deliver a child which is more or less asphyxiated, and adequate means of resuscitation should be prepared for this.

GERTRUDE DEARNLEY, M.D., B.S. Lond.,
Gynæcological Surgeon, Royal Free Hospital; Physician to Antenatal Department, Queen Charlotte's Maternity Hospital.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lts. E. J. K. Weeks and W. J. Rankine to be Surg. Lt.-Comdrs.

The following appointments are notified: Surg. Lt.-Comdrs. (D.) F. W. Paul and T. E. Brevetor to *President*, for three months' dental post-graduate course.

Surg. Lt. G. D. J. Ball is transferred to the Permanent List.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt.-Comdr. E. E. D. Gray to *Repulse*. Proby. Surg. Lt. R. St. J. Lyburn to *Concord*. Proby. Surg. Sub-Lt. W. E. Thomas to *Malaya*.

ROYAL ARMY MEDICAL CORPS.

Maj. (temp. Lt.-Col.) D. M. Corbett to be Lt.-Col., vice Lt.-Col. G. E. Cathcart (decd.).

Maj. W. J. E. Bell to be temp. Lt.-Col.

Capt. C. A. Whitfield to be Maj. (prov.).

TERRITORIAL ARMY.

Maj. H. Forrest to be Lt.-Col.

INDIAN MEDICAL SERVICE.

Maj.-Gen. G. Tate retires.

DEATHS IN THE SERVICES.

Col. Charles Mactaggart, M.B., C.M. Glasg., C.S.I., C.I.E., late I.M.S., who died at Campbeltown, Argyllshire, on Sept. 17th at the age of 69, was the son of Charles Mactaggart of that place. He received his early education at Campbeltown Grammar School, and in 1885 graduated in medicine and surgery, with commendation, at the University of Glasgow. In the following year he entered the Indian Medical Service and was in military employ till 1889, when he was transferred to the civil side of the United Provinces, and was successively superintendent of the central prisons at Benares, Agra, Allahabad, and Lucknow. In 1902 he became inspector-general of prisons, and in 1907–08 he was made a member of the Indian Factory Labour Commission. Subsequently he was made a member of the provincial legislature, and afterwards became inspector-general of civil hospitals of the United Provinces. In 1917 he was selected as president of the provincial Medical Council, and retired in 1920. He received the C.I.E. in 1911 and the C.S.I. in 1919.

DONATIONS AND BEQUESTS.—Miss Mary Reid, of Port Glasgow, left £6000 to the Greenock Eye Infirmary.—The Nottingham General Hospital has received £1500 as a result of the University College students' efforts on behalf of local medical charities.—Among other bequests, Mr. R. J. Rowat, of Glasgow, left £1250 to the Royal Alexandra Infirmary, Paisley, to endow a bed in the name of his father.—Mr. Arthur K. Meyers, of Brighton, bequeathed the whole of his property, £6033, to the Royal Earlswood Institution for Mental Defectives, Earlswood, Surrey.

BIRMINGHAM CONTRIBUTORY SCHEME.—Since the beginning of the present year the membership has increased from 366,000 to over 400,000. During the first half of the year more than 10,500 contributors and their dependents have been treated as in-patients; the out-patient attendances at the voluntary hospitals and the General Dispensary have been approximately 300,000. The district nurses have paid nearly 90,000 visits and £70,000 has been distributed among the local institutions. More than 1000 voluntary officials organise and conduct branches of the scheme in the city and surrounding districts.

PUBLIC HEALTH SERVICES

PORT SANITARY AUTHORITIES.

BRISTOL.

In his report to the sanitary authority for 1929, Dr. R. A. Askins mentions that 1021 ships arrived at the Bristol ports from foreign countries, 7136 coastwise. Of these 171 were visited by the medical officer, 2478 by sanitary inspectors. There was no case of cholera, yellow fever, small-pox, typhus, or plague. Four rat-catchers now work under the medical officer, all ships and buildings about the docks being examined systematically; 704 rats were destroyed on vessels, 5023 in docks, quays, and warehouses. Of these, 95 from ships, 177 from the shore, were examined and found free from plague. There is a refuse tip near the docks which harbours rats in spite of palliative measures; 8200 poisoned baits were laid here in May and June, but only 102 dead rats were found. Of 2478 vessels examined, 487 had sanitary defects (nature unspecified); all but two had them remedied before leaving. Thirty cases of venereal disease were received from ships and 152 cases were seen in the port clinic. Two cases of grain dermatitis, caused by a mite *Pediculoides ventricosus*, occurred in men handling barley from Saffi, in North Africa. The water-supply of the port is from the city hydrants, and in Bristol docks from a water boat, regularly inspected and cleaned. Seven samples from ships were examined and six were suspicious. Of bananas, 119,275 tons were imported more than through any other European port.

TYNE PORT.

In his report Dr. W. E. Harker mentions that of the 10,608 vessels reaching the Tyne, 9495 were inspected. Cases of diphtheria, malaria, scarlet fever, chicken-pox, and typhoid were landed; no case of plague, yellow fever, small-pox, or tubercle came to notice. Inspection showed the existence of 1119 nuisances and 1601 structural defects, including 118 verminous forecastles. Dirty crew-spaces to the number of 1043 were found, and were apparently remedied. The rats examined numbered 1900, none of them plague-infected; 1368 in 108 ships fumigated with sulphur, 2 in 8 ships fumigated with hydrocyanic acid, 530 in 20 ships dealt with by trapping methods. The food imported was generally in good condition; only 1 case of game, 5 cases of cod's roe, and 7 boxes of plaice were condemned. The tanks of 17 ships were cleaned. Leaflets on venereal disease and the facilities for treatment at the local clinics are distributed on board.

MENTAL HOSPITAL REPORTS.

THE RETREAT at YORK publishes a report illustrated as usual by charming pencil drawings and recording a busy year of work. There were 220 patients on the books at the end of December, and 63 per cent. of the 135 admitted during the year came on a voluntary basis. The death-rate was 8·5 per cent. The new property at Garrow Hill will be available for uncertified cases in a few months. The work of the occupations department increases in value and interest, and is demanding larger accommodation. A significant alteration during the year was the conversion of the last padded room into a modern bathroom. A new nine-hole golf course has been laid out. The medical superintendent discusses fashions in research and treatment, and the application of modern psychology to mental cases. Ultra-violet light therapy and general daily massage are being given a careful trial. Twelve nurses obtained their R.M.P.A. certificate during 1929.

The SCOTTISH WESTERN ASYLUMS' RESEARCH INSTITUTE publishes an outline of its history in its twentieth annual report, and once again the financial position provides a subject for grave concern. Expenses have been reduced to a minimum, and no new equipment has been added during the year. A total of 903 specimens has been examined, a very large number being from cases of general paralysis. The general conclusion is that malaria gives better results than any other form of treatment, but the benefit is enhanced by a subsequent course of tryparsamide. The laboratory provides post-graduate instruction, and a certain amount of research has been carried out on the blood-sugar reaction to insulin in the psychoses and on cases of Alzheimer's disease.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 13TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 75 (last week 106); scarlet fever, 1615; diphtheria, 1215; enteric fever, 65; pneumonia, 441; puerperal fever, 56; puerperal pyrexia, 85; cerebro-spinal fever, 7; acute poliomyelitis, 21; acute polio-encephalitis, 1; encephalitis lethargica, 22; continued fever, 1; dysentery, 11; ophthalmia neonatorum, 89. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Sept. 16th–17th was as follows:—Small-pox, 216 under treatment, 1 under observation (last week 216 and 4 respectively), scarlet fever, 1641; diphtheria, 1384; enteric fever, 29; measles, 120; whooping-cough, 113; puerperal fever, 27 (plus 13 babies); encephalitis lethargica, 118; "other diseases" 35. At St. Margaret's Hospital there were 19 babies (plus 11 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 4 (2) from enteric fever, 11 (2) from measles, 2 (1) from scarlet fever, 11 (0) from whooping-cough, 27 (6) from diphtheria, 55 (11) from diarrhœa and enteritis under two years, and 12 (2) from influenza. The figures in parentheses are those for London itself.

The deaths from enteric fever outside London occurred at East Ham and Sheffield. Liverpool reported 2 deaths from measles, Birmingham 2 from whooping-cough. Five fatal cases of diphtheria occurred at Liverpool, not more than 1 at any other large town. Seven deaths from diarrhœa were reported from Liverpool, 4 from Newcastle-on-Tyne, 2 each from Hendon, Birmingham, Coventry, Nottingham, West Hartlepool, and Gateshead.

The number of stillbirths notified during the week was 275 (corresponding to a rate of 42 per 1000 births), including 52 in London.

A DEVON CANCER BED.—An attempt is being made in Devonshire to raise £2000 for the endowment of a "Devon Bed" in the Marie Curie Hospital. The endowment would entitle women from the county to free treatment, and over £300 has already been raised.

JOINT HOSPITAL FOR SHETLAND.—The Scottish Department of Health has suggested the creation of a new 60-bed hospital at Lerwick for acute surgical, medical, and maternity cases. The total estimated cost is £54,000. The Department considers that £16,200 might be provided under the statutory services, but the remaining £37,800 would have to be made up by the Gilbert Bain Hospital Trustees and the Highlands and Islands Medical Service Fund. The proposal has now been approved by the Shetland County Council. The Gilbert Bain Memorial Hospital at Lerwick has become totally inadequate for the needs of the island.

CORRESPONDENCE

STEREOSCOPY OF X RAY FILMS.

To the Editor of THE LANCET.

SIR,—On my return from the Joint Tuberculosis Council Canadian Tour, I think it well to make the following comment on a subject which gave rise to considerable and keen discussion at almost every medical gathering in which we had the honour and pleasure to take part. I refer to the supposed value of the application of the principle of stereoscopy to the examination of X ray films.

The appearance of solidity obtained by the observation of stereoscopic photographs with both eyes involves the use of a little understood process, by which the brain fuses the images received on each retina into one image, which has an entirely new attribute of distance or depth. If we perform the simple experiment of looking at a drawing-pin point uppermost, we shall see a circle of brass with a pin taking up the position of the radius of the circle. If the pin is immediately in front of the observer, with the left eye the image of the pin appears to the right of the vertical, with the right eye to the left of the vertical. With both eyes in use the pin is seen to assume a medial position carrying with it a correct impression of its relation to the head of the pin, though we are well aware that neither retina receives the image as seen by binocular vision.

Wheatstone first explained the use of the stereoscope in the beginning of the last century, and by means of this instrument two dissimilar plane images are placed in sufficient proximity to allow them to fall on homologous points on the two retina so that fusion takes place and an impression of solidity results. Appreciation of distance is so important that this faculty of fusion of images is in constant daily use. Small wonder, then, that the use of a stereoscope requires very little practice, and that on the first occasion on which a stereoscope is used it conveys what is intended—an impression of solidity.

But in order that this solidity should be a recapitulation of the solidity of the object of which the plane stereoscopic image is a representation, this image must contain a record of the perspective of the original object. That is to say, it must be a diagram or a photograph, and not the mere shadow of some three dimensional object on a plane surface. Everyone is familiar with pictures of a series of similar objects each diminishing in size until they disappear into infinity. Two photographs of such a series would form an excellent pabulum for the production of a solid image in a stereoscope, but the X ray record of such a series would result in a large image of the object furthest from the film and a small image of the object in close apposition to the film.

Now when this film is examined in a stereoscope, the largest shadow gives the impression of proximity and the small shadow of distance, and thus the solidity is reversed. It is true that an impression of solidity can be obtained by the stereoscopic examination of X ray films, but it is obviously impossible for this impression to convey a true indication of the three dimensional relationship of the objects whose shadows are recorded on the films. If X rays were amenable to refraction as light waves are, this might be another story.

At present all we are doing by the observation of X ray films in a stereoscope is to use a series of shadows to create an illusion, and because it is an illusion which we have all used daily since birth we are inclined to accept the result without question.

I am, Sir, yours faithfully,

LEONARD STOTT,
Assistant Medical Officer, Papworth Village Settlement.

Cambridge, Sept. 17th, 1930.

TREATMENT OF PULMONARY TUBERCULOSIS IN SWITZERLAND.

To the Editor of THE LANCET.

SIR,—I hope you will allow me to reply to the letters provoked by my reflections of July 19th. Statistics, as the President of the Royal College of Surgeons has put it, "can be made to show anything, even the truth"; thus while the meteorological figures quoted have no doubt demonstrated a bald truth, that Switzerland has more sun in winter than England, the inference that therefore Switzerland has the advantage over England as a place to treat phthisis is not justified. If the high Alps are more healthy than England we should expect the natives of those parts to be of finer physique than the natives of England, which is not so—in fact, quite the reverse.

Dr. Amrein, writing from Switzerland, refers to our climate in terms of a sunless, treacherous, misty, and damp winter, and I notice to my sorrow that he is supported in this error by an Englishman, Dr. Banks, and also by the patient of "M.R.C.S." On some people, a bad day in England seems to make an indelible impression, so that they imagine the weather is always bad. Similarly, some people "always" just miss the 'bus, or "always" find a lost article in the last pocket searched. Yet these people who run down their own climate will tolerate appalling weather in Switzerland with equanimity, presumably because they have been taught that the Swiss weather is always good. If Dr. Banks believes, as his letter seems to imply, that patients can get, or usually do get, medical and surgical treatment in Switzerland superior to that at home, he has a reason which might well outweigh all others in impelling him to recommend Switzerland; but I do not think the belief is common. The majority of medical men who have recommended Switzerland have done so, I think, from climatic considerations, and it is on this point in particular that English-informed opinion is undergoing a change. Montana has been specially mentioned in this correspondence. I have visited Montana and I can agree that, owing to its peculiar situation, the facilities for walking exercises are moderately good, and also that it is a quiet little town; but in the main (and surely it is no crime to make a modest generalisation) Montana conforms to the generality of other Swiss resorts situated at similar altitudes.

I am surprised to read that Dr. Hudson would have us regard the commercial success of the Swiss régime as proof of its efficacy. One can imagine a layman basing his judgment on this consideration, but every doctor knows how worthless this may be. I do not say that good results of treatment are not obtained in Switzerland—any place almost may show good results provided the doctors in charge understand their work; but I do believe the task imposed on doctor and patient is more difficult if undertaken in Switzerland than in England, and I am very pleased to read that

no less an authority than Dr. Vere Pearson holds the same opinion. Dr. Pearson calls our attention to the pronouncement of Sir Henry Gauvain in which the latter explains that a healthy climate is one which possesses frequent changes of weather from warmth to coolness, and sunshine to shade (the very qualities, in fact, that we enjoy in England both summer and winter), and that patients soon cease to react beneficially to prolonged weather of one type. An instance of the truth of this teaching is clearly seen in the case of the white man forced to live in the tropics, where sunshine and ultra-violet light ad nauseam do not maintain him in a high plane of health, and do not protect him against tubercle.

In England we have a generous, varied, and interesting climate. We have a medical tradition of sound learning and honourable practice as strong to-day as ever before. Why, then, as Dr. Davis asks, should we "banish our phthisical patients to a foreign country where home comforts and familiar ways are absent"? That there are reasons for not doing so I hope I made clear in my article.

I am, Sir, yours faithfully,

W. R. E. HARRISON.

Alexandra Hospital, Swanley, Kent, Sept. 22nd, 1930.

THE MEDICAL TREATMENT OF CANCER.

To the Editor of THE LANCET.

SIR,—My letter in your issue of Sept. 13th (p. 611) pointed out that, within a week of my provisional announcement of the use of lead selenide in the treatment of cancer, Prof. Blair Bell wrote a letter suggesting priority. Although there is no mention of selenium in his writings prior to the date of my article—i.e., March 12th, 1927—he has, until last week, regarded colloidal lead selenide simply as a variant of his "colloidal" lead treatment. Of a set purpose, but with absolute truth, my letter of Sept. 13th stressed my opinion as to the relatively greater importance of selenium; Prof. Blair Bell writes immediately to claim priority as regards this discredited element also. I think that his own writings are the best evidence as to the truth; particular attention should be paid to his dates.

Prof. Blair Bell has left the record: "For a time," he wrote,[1] "we used a suspension of lead selenide, but this appeared to be almost too stable to give good results, although it is not inert; it is, however, singularly atoxic. Lead selenium has, however, been successfully employed *by Dr. Todd, of Bristol, who was the first to make and use this preparation of lead.*" [The italics are mine.] Here he definitely affirms that I first made and used lead selenide. Now, as I have said, I published the first account of the use of lead selenide in your columns[2] on March 12th, 1927. In the very next issue of THE LANCET, a letter appeared from Prof. Blair Bell stating that his chemists had had no difficulty in making lead selenide; but what had been a "suspension" in 1929 improved and became an "excellent colloid" in the repetition of his letter of 1927 which appears in your issue of last week (p. 667).

Still further complications emerge from this last letter, for now Prof. Blair Bell says: "However, for the information of Dr. Todd, I may say that we commenced the manufacture of lead selenide *in October, 1926* [italics mine]. . . . We found, as I have said before, that this preparation is of little value. . . ." Since Prof. Blair Bell himself affirms that I was the first to make and use lead selenide—i.e., March 12th, 1927—I am unable to understand how he prevailed upon his chemists to make it in October, 1926, and I cannot see how he was able to treat a patient (Case R.I. 70[1]) with this preparation in February, 1927.

I am, Sir, yours faithfully,

Bristol, Sept. 20th, 1930. A. T. TODD.

PRURITUS ANI ET VULVÆ.

To the Editor of THE LANCET.

SIR,—I have read with interest the letter on this subject in your issue of Sept. 13th by L. F. R. Knuthsen and Howard Humphris, and I note that they strongly advocate the use of X rays in the treatment of this condition.

I feel very strongly that this statement should not be allowed to go unchallenged. My own experience, which is not inconsiderable, is that X ray treatment is very dangerous in these cases. I have seen some terrible results from X ray burns in the anal region during the last 15 years, and consider such treatment quite unjustifiable in view of the risks involved. I have seen two cases of rapidly developing epithelioma as a direct result of X ray treatment for pruritus ani, and in both cases extensive resection of the parts had to be performed in an effort to save the patients' lives. In a number of cases I have had to treat bad burns, which have caused months of suffering. These results were not always due to careless or inexpert administration of the rays, as some of these patients had been treated for pruritus by men whom I know to be thoroughly expert in the use of rays. There would seem to be a special liability for the skin in the neighbourhood of the anus to undergo X ray burning in certain persons, and this liability cannot be estimated or allowed for.

While undoubtedly cures can sometimes be effected by the use of X ray application, I consider the risks are so great that the treatment is unjustifiable. No such risk is involved in operative procedures. The risk also of sterilising young persons is not so easily or certainly avoided as the authors would have us believe. The bad results from X ray treatment for very obvious reasons do not get reported, but I have seen too many of these results, and I feel strongly that the profession should be warned that they do occur.—I am, Sir, yours faithfully,

J. P. LOCKHART-MUMMERY.

Hyde Park-place, W., Sept. 19th, 1930.

COG-WHEEL BREATHING.

To the Editor of THE LANCET.

SIR,—I was extremely interested in Dr. Hebert's article in your last issue (p. 628), as it agrees so fully with the theory I have tried to place before younger members of the profession and students when giving instructions here in physical signs—except in one point. In cases of congestion of small areas of the lung, as in tuberculous lesions, one can almost invariably find the vocal fremitus increased; may not the sound produced by the systole of the heart, in suitable cases, be equally well conducted to the stethoscope with the abnormal breath sounds? I have frequently put this forward as one of the causes of so-called cog-wheel breathing on purely

theoretical grounds, without the scientific proof which Dr. Hebert has applied in his cases; and I think it is worthy of consideration.

I am, Sir, yours faithfully,

A. ADAMS, M.D.,
Medical Superintendent, Liverpool Sanatorium,
Sept. 23rd, 1930. Frodsham.

A PERVERSION OF TASTE.

To the Editor of THE LANCET.

SIR,—I was recently called in by a colleague to give an opinion in what proved to be a case of cerebellar tumour. Beside the more or less usual focal symptoms was one that I have not previously encountered in this connexion. The patient found that everything given, solid or liquid, tasted sweet. A cerebellar growth extending forward to the pons and involving the seventh nerve would have to be much more extensive than was the case here, and, moreover, abolishes the sense of taste altogether, with, I believe, no more than a temporary perversion. if indeed any. This patient's abnormal taste sense was definite and constant for both anterior and posterior lingual surface and persisted till the end. Of course, anyone having had special experience amongst the insane and mental defectives is familiar enough with taste perversion and more particularly in the psychosis of general paralysis; personally I have twice only met with the special perversion alluded to, and then it was transient and not very pronounced. One case was a general paralytic; the other an elderly and somewhat demented alcoholic patient. The parageusia of the pellagra sufferer is, as far as I can learn, always the *mal salso*, and I only refer to it as an instance of special and consistent alteration of taste. I shall be very grateful for any enlightenment on this particular case and for any information on the subject of taste perversion.

I am, Sir, yours faithfully,

Whitehall Court, S.W., Sept. 21st, 1930. G. AUBREY.

PANEL AND CONTRACT PRACTICE

Cost of the National Service.

FIGURES given [1] by the Minister of Health indicate the extent and cost of the insurance medical service in England in 1929. There were 14,600 doctors in insurance practice. Medicines and appliances were supplied as part of medical benefit at about 9000 chemists' shops. The number of insured persons entitled to medical benefit was a little over 14,000,000. Medical benefit cost over £8,666,000. Of this sum panel doctors received over £6,256,000 in respect of their duties of attending and treating insured persons; and £1,922,800 of the balance was paid to panel chemists for the supply of drugs and appliances. About £200,000 was paid to country doctors on account of mileage—i.e., in practices where the physical conditions are such that distances covered are not in themselves a fair measure of the doctors' difficulties. Nearly £10,000 was set aside to enable country doctors to attend courses of post-graduate study, and to provide them with facilities such as maintenance of telephones, motor-cars, and branch surgeries. Doctors received about £194,800 for medicines and appliances supplied by them as part of emergency treatment, for medicines administered by them personally, and for medicines dispensed by them in country districts where patients are out of reach of chemists. Finally sums of about £71,000 and £11,000 were paid on account of insured persons who elect to obtain treatment (including medicines) through approved medical institutions, or with the consent of insurance committees to make their own arrangements for treatment.

Investigation of Prescribing.

Last year regional medical officers of the Ministry of Health paid 1325 visits (125 more than in 1928) to doctors whose prescribing appeared to call for explanation, and this exchange of view, Mr. Arthur Greenwood tells us in his report just issued,[1] enabled him in the great majority of cases either to accept the explanations tendered by the doctors, or to satisfy himself that minor departures by the doctors from a reasonable standard of prescribing would not recur. In about 145 cases the Minister informed the doctors concerned that while it appeared to him that, notwithstanding their explanations, there was a prima facie case for referring the matter to the panel committee, he would refrain from doing so because he was satisfied of their intention to prevent any question of such reference from arising in the future. In 16 cases (against 31 in 1928) it was referred to panel committees to find whether the prescribing had imposed charges on the available funds in excess of what was reasonably necessary, and, if so, of what amount.

In 11 out of 12 of these cases in which the panel committee's findings were available before the end of the year, and in five out of the six cases outstanding from last year, panel committees found that an excess cost had been so imposed during the quarterly periods which were the subject of investigation. In 14 cases the estimated amounts of excess cost found by the panel committee varied from so small a sum as £1 1*s*. 5½*d*. to £100. In two cases the committee made no findings as to the amount of the excess cost imposed, and in the remaining two cases the committee found that there had been no excess cost.

One appeal was made by a doctor against the panel committee's decision; in six cases the Minister was dissatisfied with the committee's findings; and in two cases both the doctors and the Minister, on different grounds, decided to carry the matter further. In these nine cases three medical men, independent of the Ministry, were appointed by the Minister to act as referees on the points at issue. In one case the report of the referees was outstanding at the end of the year. In seven of the eight cases dealt with by them the referees reported that excess costs, varying in amount from £5 5*s*. 0*d*. to £150, had been imposed upon the available funds by the doctors' prescribing. In one case the referees concurred with the finding of the panel committee that no excess cost had been imposed. In the one case outstanding at the beginning of the year the referees reported that an excess cost had been imposed.

After considering the recommendations of insurance committees made in the light of the findings of panel committees or referees, or both, and giving the doctors concerned an opportunity of making oral or written representations, it is, says Mr. Greenwood, his duty to decide what amount of money, if any, it is equitable to withhold from the remuneration of the doctors concerned, on the ground that they have prescribed in such a way as to throw upon the available funds a charge in excess of what was reasonably necessary for the adequate treatment of their insured patients. Actually he withheld money under this procedure in

[1] Eleventh Annual Report of the Ministry of Health, 1929–30. Cmd. 3667. H.M. Stationery Office. 4*s*. 6*d*.

22 cases, the sums withheld ranging from £5 to £150, and amounting in all to £643 10*s*.

Limiting the Cost of Prescriptions: Effect on the Patient.

A practitioner in the Home Counties writes:—

"There has recently been a good deal of perturbation regarding the activities of the Ministry of Health in their endeavours to keep down the cost of panel practitioners' prescriptions. One aspect of the matter has not, I think, received the attention that is its due. This is the effect on the patient, for whose benefit after all the whole scheme of national health insurance exists. Let us consider how the present state of affairs affects him.

"It is now, I believe, the custom for doctors whose prescriptions are above the average to be visited by an official from the Ministry of Health who demands details and reasons both generally and in regard to individual prescriptions. This, with its implied threat of a heavy fine (and recent occurrences have shown it to be no idle threat), involves a considerable amount of worry and anxiety to the doctor. The result is obvious. In a number of cases the doctor determines that whatever happens he will not be so worried again, and proceeds ruthlessly to cut down all prescriptions. This has two effects. One is in operation now, and is that the patient may be deprived of actual necessary treatment by a doctor whose thoughts are on his averages. The other, which is really more serious for the patient in the long run, is the influence of this restriction on the doctor's mind; so that from being a keen enterprising man always on the look out for new and useful treatments he is in danger of becoming a mere drudge whose sole object is to secure a living.

"I do not think that this picture is overdrawn. I feel that it represents only too well what is beginning to happen to me and my patients. If it is not overdrawn, then, I think, one may fairly say that we are not doing our duty to the public unless we tell them plainly the facts of the case. It should not be forgotten that panel practitioners as a body hold a very important and responsible trust in regard to the treatment of a considerable proportion of the population of the country."

Departmental and Legal Standards.

The Minister of Health continues to issue the reports of inquiry committees constituted under Part VI. of the National Health Insurance (Medical Benefit) Consolidated Regulations, and his decisions thereon. It is instructive to compare the departmental standard expected of the panel practitioner with the legal standard enforceable in either civil or criminal proceedings in a court of law.

In a recent case where the Middlesex Insurance Committee alleged neglect of a panel patient, the facts were found as follows. A general labourer, aged 25, was taken ill on May 12th, 1929. In the previous week he had been bitten on the cheek by an insect; on May 12th he also complained of pain in the side. On May 13th he did not go to work, but visited the respondent practitioner, who gave him a prescription for a tonic and advised him to continue poulticing his cheek which the patient had already been doing. The patient took the medicine, went to bed, and by the evening became somewhat comatose. Next day (the 14th) he was obviously worse; his mother sent at 5 P.M. for the practitioner, who arrived shortly before 6 P.M. The practitioner, according to the Inquiry Committee's findings, "made a somewhat cursory examination of the patient: the pulse was felt but there was no taking of the temperature or sounding of the lungs." As to the pain in the side, the practitioner offered no definite opinion, but hazarded the suggestion that it might be due to pleurisy; he promised to call next day. The patient grew worse; next day he complained of severe headache, and the inflammation from the bite spread from the cheek to round the eyes; he was also becoming more drowsy. The respondent practitioner did not appear; the mother, being extremely anxious, sent her daughter with an urgent summons for him at about 8 P.M.; he came shortly before 10 P.M. On this occasion again, says the Inquiry Committee's report, no proper physical examination was made beyond taking the pulse. He told the mother the condition of continued pain in the side was very serious, and he would make arrangements for the patient's removal early next day to the hospital. At night the patient was very seriously ill and delirious. Early next day (the 16th) the mother sent for another doctor, who recommended immediate removal to the hospital. The respondent practitioner did not call on this day. In the early afternoon the patient was removed to Isleworth Hospital; he died before midnight. There was no post-mortem examination; death was certified as due to facial erysipelas and meningitis.

Upon these facts the Inquiry Committee finds "negligence of a somewhat serious character" in (*a*) inefficient and insufficient examination of the patient at the two visits (and in particular, the omission to use thermometer or stethoscope); (*b*) the failure to call on the 15th until the evening (the Committee says the patient's condition on the 14th warranted the respondent's attendance on the 15th without special summons); and (*c*) the unexplained failure to arrange for the removal to hospital (as promised) in the early morning of the 16th. At the same time the Inquiry Committee observes that the charges related to one patient only out of a panel list of about 2500—a number which, it is hinted, may have some relevance to the amount of attention the practitioner could give to each individual. There was no general charge of negligence or prejudicial conduct. The respondent himself was in bad health at the material dates. On the 16th he was visited by a fellow-practitioner, who found him suffering from congestion of the lungs, and recommended him to stop work. On the 16th the practitioner instructed his bookkeeper to communicate with another fellow-practitioner to see his patients for him; but the message, if sent, was ineffectual. It is clear from a letter written by a reputable insurance company—which evidence the Inquiry Committee mentions with a caution unnecessary in what is after all only a quasi-judicial tribunal—that the respondent received compensation for incapacity for the period from April 18th to May 2nd. The Inquiry Committee justly states that the patient's death cannot be directly attributed to the act or default of the respondent; the patient's condition may have presented complicated and unusual features, and the deceased might not have responded to the most careful treatment. From the point of view of criminal proceedings before a jury, the absence of a post-mortem report would have been decisive; a genuinely judicial tribunal cannot penalise a practitioner upon hypothetical grounds. The respondent, however, was not being tried for manslaughter or sued in damages for neglect. He was faced with a complaint that he had not maintained the standard expected of a panel practitioner. The Inquiry

Committee finds the Insurance Committee's complaint justified and recommends that the practitioner be made to pay the taxed costs of the inquiry. The Minister's decision embodies this recommendation, and adds a fine of £50 in the usual form of withholding that sum from monies payable to the Insurance Committee and deducting the amount from the practitioner's remuneration. Two other points may be mentioned. The respondent asked for an adjournment at the opening of the inquiry, but this was refused apparently on the ground that he had made no earlier communication to this effect. He may have been at some disadvantage in consequence. Practitioners in a similar position may note that it is well to give early notice of a desire for a postponement; otherwise the Insurance Committee's witnesses attend and all is ready, and the inquiry at that stage cannot be adjourned without inconvenience. The second point is that there was an allegation that the respondent was drunk or under the influence of drink when he visited the patient on the night of the 15th. The Inquiry Committee's report acquits him of this grave charge for which there was evidently no ground. It seems unfortunate that charges relating to events in May, 1929, were left undisposed of till July, 1930.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

THE LEGAL POSITION OF THE SURGEON.

THE problem of surgical interference, as viewed by the law, was recently discussed by Prof. Fritz Reuter at a meeting of the Medical Union of Graz. The law requires that before an operation the patient should give his written or oral consent. As a rule, the patient or a responsible member of his family is advised of the necessity of an operation, and, if he agrees, this is taken as valid consent. In certain instances, especially if the operation may necessitate removal of important structures or organs besides the one manifestly diseased, the surgeons, even in hospitals, are accustomed to obtain written permission to operate according to their best knowledge, so far as they find it necessary, even if a mutilating operation is required. Of late an additional factor has been brought into action by the frequent performance of sterilising operations on both sexes. It may be pointed out here that the Austrian law distinguishes two kinds of operations in this respect: sterilisation and castration. The first group comprises operations which spare the inner secretion and the faculty of cohabitation, while the second group comprises those which destroy all the functions of the sexual glands. Prof. Reuter pointed out that the indication for operation is or may be triple: medical, social, and eugenic reasons are recognised, but the last two are as yet not distinctly worked out. All authors of medical legislation agree that the faculty of fecundation is a right which is protected in all States, although it is not clear what reasons actually prompt the State to protect its citizens in this way—whether it is on militarist, religious, ethical, or rational grounds. Legal sterilisation, as practised in some of the United States and in Denmark, especially on criminals and the insane, has not been in operation long enough to give reliable answers. Prof. Reuter denied the legality of the social or economic indication for sterilisation of an otherwise healthy male or female; he pointed out that only recently a surgeon was heavily fined for performing such operations wholesale in Graz,[1] and that in an action brought against a gynæcological clinic in Vienna for removal of the ovaries of a woman without her knowledge, the surgeons were found guilty. Only the sterilisation of mentally defective persons of both sexes is regarded as an undoubtedly legitimate social indication. But even here a committee of qualified persons should be previously asked to give a written report and unanimous recommendation. The law of 1927 requires also the consent of the other party of a married couple in case of a sterilising operation, and stipulates the possibility of divorce if one party was sterilised before marriage and did not disclose this fact before the union. Prof. Reuter appeals to the medical profession to stick to the medico-biological standpoint, and save as much as possible of the most important function of the human race. We should not be led away, he thinks, by economic and social indications, which are often only transient.

[1] See THE LANCET, 1929, ii., 1281.

DISEASE, DEATHS, AND BIRTHS IN AUSTRIA.

The September report of the Austrian Board of Health gives an extensive survey of the health of the people during 1929. The population of the Republic was 6,536,892, and of Vienna 1,886,147; in other words, 30 per cent. are massed in a single city. The number of deaths in Vienna was 26,682, as compared with 25,811 in 1928, while in the whole Republic it rose from 96,321 to 97,377. Of these, 2702 (611) were due to accidents, 2434 (1044) to suicide, and 199 (75) to murder. (The figures in parentheses are those for Vienna itself.) The commonest cause of death was circulatory disease, which claimed 16,606 (6025) victims, as against 15,780 (5628) in 1928. Second in frequency ranks malignant disease, which rose to 10,587 (3639) from 10,239 (3607) in the previous year, while tuberculosis comes third with 10,046 (3364). The figures reveal a constant decline of tubercle and a notable increase of heart disease and new growths. Of the infectious diseases, diphtheria with 624 (217) deaths shows a considerable increase over 1928. Puerperal fever accounted for 263 (126) deaths, while typhoid caused 161 (45), scarlet fever 122 (75), measles 195 (39), and whooping-cough 157 (14), as against 455 (97) in the previous year. No case of small-pox, typhus, or asiatic cholera was notified during 1928 or 1929.

The number of stillbirths was 3109 (525); infantile deaths numbered 5712 (739) in the first month of life, and 12,494 (1449) before the end of the first year, as compared with 13,964 (1750) in 1928. But births have simultaneously fallen from 119,979 (20,158) to 113,280 (17,144).

In the agricultural districts the deaths of infants and children up to 5 years comprise over half of all deaths, whilst in the industrial parts and in Vienna these deaths form only about 15-25 per cent. (in Vienna alone only 14 per cent.) of the total. Another interesting feature in this year's report is the item: "Born under the aid of qualified midwives or medical men." In Vienna for many years every child has fallen under this heading, and in the whole Republic only about 4 per cent. of births have taken place without such assistance.

LADIES' MEDICAL GOLFING SOCIETY.—At the autumn meeting held at the Ashford Manor Golf Club on Sept. 23rd the Cecil Leitch Prize for a medal round on handicap was won after a tie by Mrs. Roberts Harris (80), who also won the first division handicap prize, Miss Roberts Harris being second. The scratch prize was won by Mrs. Cavendish Fuller (87) and the captain's prize by Mrs. Massey (156 for two rounds). Mrs. Oldershaw (80) won the second division prize and Miss M. Hamilton (84) and Mrs. Hobson (90) the third division prizes. In foursomes Mrs. Marriage and Mrs. Dudgeon were first and Mrs. Roberts Harris and Mrs. Fletcher second.

OBITUARY

SIR NEVILLE HOWSE, V.C., F.R.C.S. Eng.

The death of Sir Neville Howse in London on Sept. 21st ends a distinguished career in medicine, the army, and in the political life of Australia.

Neville Reginald Howse was born 67 years ago, the son of Dr. Alfred Howse, of Stogursey, near Bridgwater in Somerset, and was educated at Fulland's School, Taunton. Entering the London Hospital he qualified as M.R.C.S. in 1887, and went out to Australia. In 1896 he came back to the hospital as house surgeon, and in 1897 was admitted to the Fellowship of the Royal College of Surgeons. Returning once more to Australia, he practised for a couple of years in New South Wales, but his work was soon interrupted by the South African war. Volunteering in October, 1899, he later held a captain's commission in the New South Wales Medical Staff Corps, and saw much service in the Orange River Colony and the Transvaal. He was awarded the Victoria Cross for gallantry during the action at Vredefort on July 24th, 1900, when he carried a wounded man to safety in face of heavy cross-fire.

After the Boer war Howse practised at Orange, in New South Wales, and with success. In 1914, however, he was again called upon for military service, and was appointed principal medical officer to the Australian Naval and Military Expedition to New Guinea and the Pacific Islands. When this expedition returned he went to the Dardanelles as A.D.M.S. to the 1st Australian Division, and was in charge of the medical arrangements at Anzac. For his work at Gallipoli he was mentioned in despatches and created C.B. When the Peninsula had been evacuated he came to England as Director of Medical Services, Australian Imperial Force, and in 1917 was promoted K.C.B. His work in France was of conspicuous value, and after the war he was further honoured by being made K.C.M.G. In 1921 he was appointed Director-General of Australian Army Medical Services, but he retired in the following year with the rank of major-general. His public service, however, was by no means at an end, for he was at once elected to the Commonwealth House of Representatives, and later held office as Minister for Home and Territories, as Minister of Defence, and as Minister of Health. He was one of the Australian representatives at the Fourth Assembly of the League of Nations in 1923, and it was at one time thought that he might succeed Sir Joseph Cook as High Commissioner in London. He remained in close touch with some of his old friends at the London Hospital, and attended the annual dinner a couple of years ago.

Sir Neville Howse married in 1905 Evelyn Northcote, eldest daughter of G. de Vial Pilcher, of Newstead, Orange. They had two sons and three daughters.

ROBERT WILLIAM MACKENNA, M.D. Edin.

WE have to record that Dr. R. W. MacKenna, dermatologist to the Liverpool Royal Infirmary, died on Sunday last at the age of 56. He was widely known not only in his specialty but as a novelist, and his death will be deeply regretted.

The son of the Rev. R. MacKenna, minister emeritus of the Martyr's Church, he was educated at the Dumfries Academy and the Edinburgh High School and graduated both in arts and medicine at the Edinburgh University, proceeding to the M.B. degree in 1898. Later he did post-graduate work on the Continent. His practice at Liverpool was at first a general one, but within a few years he began to devote himself exclusively to dermatology and he was soon elected assistant physician to the Liverpool Skin Hospital. He became one of the leading specialists in Lancashire, and in 1919 was appointed to the staff of the Royal Infirmary and lecturer in the University. He was also consulting dermatologist to the Cancer and Skin Hospital and a keen supporter and valued member of the Liverpool Medical Institution. For some years he was the general secretary and he was largely responsible for the resuscitation and success of the *Liverpool Medico-Chirurgical Journal* of which he was an exceptionally active editor.

An intense and enthusiastic worker and an excellent teacher Dr. MacKenna embodied much of his experience in the well-known text-book of dermatology which bears his name. Further, he was a witty and ready speaker, and a welcome guest at many civic functions.

"It is difficult," writes Prof. R. E. Kelly, "to appreciate the loss Liverpool has sustained in MacKenna's death. Quite apart from his professional reputation, which was deservedly high, he had a genius for friendship which endeared him to everyone to whom he spoke. I know of no one who was so universally loved. It is difficult to exaggerate the amount of work he did, not only for his patients, but also for a generation of medical students whose training seemed to be one of the pleasures of his life. He spent laborious days in making and painting a collection of wax models illustrative of his work, and he wrote a text-book which for clarity, wisdom, and artistry remains unsurpassed by any English text-book. But perhaps it was not as a doctor that MacKenna would wish to be remembered. He had an absorbing interest in literature and this, with his own mastery of words, led him during the war to 'scribble' as he used to put it. The change from a consulting practice in Rodney-street to a hospital in France first impelled him to take up his pen, and in the 'Adventure of Death' he scored his first success. This was followed later by the 'Adventure of Life.' These were studies rather than stories, some, poignant in their intensity, suggested by what he himself had seen during the war. Then came the novels 'Flower o'the Heather,' 'Through Flood and Fire,' both tales of the Border, of the Covenanters and their persecutors. And then 'Bracken and Thistledown' and 'O Rowan Tree,' tales of Scottish village character filled with that Scots humour which always seems to need a little dialect to tincture it. In this milieu he fitted perfectly. The spirit of the Border was bred in his bones. MacKenna often said that 'Through a Tent-door' was his best book. It certainly reflects his philosophy, for to him throughout life charity stood first."

Dr. MacKenna's war service was with the 57th General Hospital B.E.F., where he acted as physician and dermatologist. He married Dr. Harriet Amelia Scott Bird, daughter of the Rev. Charles Bird, rector of Castle Eden, and leaves one son, Dr. R. M. B. MacKenna, who is also a dermatologist.

UNIVERSITY OF DURHAM.—At the opening of the winter session of the College of Medicine on Thursday, Oct. 9th, an address on the Genesis of the Physician's Ideal will be given, at 4.15 P.M., by the Bishop of Durham, Visitor of the University.

MEDICAL NEWS

University of Birmingham.

Medals and prizes will be presented to students of the Faculty of Medicine on Monday, Oct. 6th, at 5 P.M., in the Medical Lecture Theatre, Edmund-street. An address to students will be given by Prof. Priestley Smith, F.R.C.S.

Lectures on Industrial Psychology.

The London School of Hygiene and Tropical Medicine announce the following special lectures by Dr. Millais Culpin, Consultant to the Industrial Health Research Board:—Sept. 29th: Importance of Psychological Aspects of Illness. Oct. 1st: Psychology—the History of Medical Views; 6th: Psychology—Nomenclature and Classification; 8th: Psychology—the Incidence of Symptoms, the Occupational Neuroses; 13th: Psychology—Theories of Psychopathology; 15th: Psychology—Theories Concluded. The lectures are open free of charge to members of the public health service and others interested in public health work. They will be given at 3 P.M.

Post-graduate Work in Manchester.

The post-graduate programme for Manchester for the year 1930–31 has been arranged in part by the Faculty of Medicine of the University and in part by the staffs of the hospitals working in coöperation. Courses are to be given in ophthalmology (October), dermatology (February), operative surgery (October), bacteriology (October). It is hoped that the highly successful course in obstetrics given by the staff of the St. Mary's Hospitals will be repeated in June. Clinical assistantships are available in special subjects, including radium therapy. Ancoats Hospital affords clinical teaching every Thursday morning, open to all practitioners who care to come. In the afternoons the Royal Infirmary will hold its usual lectures by members of the staff and others on Tuesdays and Fridays, and Ancoats Hospital on Thursdays.

The Lloyd Roberts Lecture for the year will be given by the Bishop of Birmingham on Friday, Nov. 7th, in the Physiological Theatre of the University. His subject will be Heredity and Predestination.

Proposed Medical Socialist Organisation.

A meeting was held at the National Labour Club on Sept. 21st to discuss the formation of a medical socialist organisation. Dr. M. I. Finucane, J.P., was called to the chair, and Dr. C. W. Brook (London), convener, read letters of apology for absence from Dr. Drummond Shiels, M.P., Under Secretary for the Colonies, Mr. Somerville Hastings, M.P., and Dr. Stella Churchill, L.C.C. Dr. Brook said he had received a letter from Dr. Ewald Fabian, of Berlin, informing him that an International Union of Socialist Physicians was about to be created; strong national medical socialist bodies were in existence, and regret was felt that in England there was no similar organisation. The creation of a British organisation was, Dr. Brook continued, justified on several grounds: (1) as a means of pressing for the establishment of a properly organised national health service, (2) as a means of contact through the International Union with other national organisations, (3) as a means of devising legislation for the benefit of the health of the workers and of bringing pressure on the authorities to carry such legislation into effect, (4) as a means of propagating socialism among the medical profession—he would admit students as associates and thus carry the campaign into the medical schools, (5) as a means of working as an organised body of socialists within existing medico-political organisations, and (6) as a means whereby medical men and women who for economic reasons cannot join a local Labour Party or I.L.P. branch, can become affiliated members of the Party. In the discussion which followed, Dr. F. G. Bushnell (Plymouth) suggested that such an organisation would assist the workers' health committees now in process of formation by the I.L.P. Dr. Menon promised the organisation the support of Indian medical practitioners in this country, Dr. P. Macdonald (York) said that while he was in favour of the extension and improvement of the existing voluntary hospital system, he would support the establishment of such an organisation. Miss Esther Rickards, M.S., L.C.C., thought it would prove useful to Labour members of committees of municipal hospitals, and to the medical advisory committee of the Labour party. A resolution in the following terms: "That the members of the medical profession whose political views are in agreement with those of the Labour party and with the ideals of socialism be organised as a political body and that a committee be formed to draw up a constitution for this body and that this draft be submitted to a meeting of all those medical men and women known to hold political views in accordance with those of the Labour party and with the ideals of Socialism" was proposed and carried unanimously.

Medical Diary

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Sept. 29th, to SATURDAY, Oct. 4th.—METROPOLITAN HOSPITAL, Kingsland-road, E. Special Post-graduate Course in Medicine, Surgery, and the Special Departments, occupying from 10.30 A.M. to 5.30 P.M. Further particulars from the Fellowship of Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Sept. 29th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose, and Throat Clinics. Operations.
WEDNESDAY, Oct. 1st.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Throat, and Ear Clinics. Operations.
FRIDAY.—10.30 A.M.: Ear, Nose, and Throat Clinics. 2.30 to 5 P.M.: Medical, Surgical, and Children's Diseases Clinics. Operations.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.
MONDAY, Sept. 29th.—10 A.M. to 1 P.M., Surgical Ward-, Genito-Urinary Operations, Skin Department. 2 P.M., Operations, Surgical Wards, Medical, Surgical, Eye and Gynæcological Out-patients.
TUESDAY.—10 A.M. to 1 P.M., Medical Wards, Clinical Demonstration (Surgical Dental Department). 2 P.M., Operations, Medical, Surgical, and Throat Out-patients.
WEDNESDAY, Oct. 1st.—10 A.M. to 1 P.M., Medical and Surgical Wards, Children's Medical Out-patients. 2 P.M., Gynæcological and General Operations, Medical, Surgical, and Eye Out-patients.
THURSDAY.—10 A.M. to 1 P.M., Neurological Out-patients, Demonstration of Fractures. 2 P.M., Operations, Medical, Surgical, and Genito-Urinary Out-patients.
FRIDAY.—10 A.M. to 1 P.M., Medical Wards, Skin Department, Dental Department, Clinical Demonstration (Medical). 2 P.M., Operations, Medical, Surgical and Throat Out-patients.
SATURDAY.—10 A.M. to 1 P.M., Throat Operations, Bacterial Therapy Department, Medical Wards, Children's Medical and Surgical Out-patients.

ST. MARY'S HOSPITAL POST-GRADUATE COURSE.
FRIDAY, Oct. 3rd, to SUNDAY, Oct. 5th.—Lectures and demonstrations beginning at 10.15 A.M. daily, and continuing till 4 P.M. on Friday and Saturday, and 12.45 P.M. on Sunday.

CHARING CROSS HOSPITAL POST-GRADUATE COURSE.
SATURDAY, Oct. 4th, and SUNDAY, Oct. 5th.—Lectures and demonstrations from 9.30 A.M. till 4.15 P.M. on Saturday, and from 10 A.M. till 4.45 P.M. on Sunday.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.
FRIDAY, Oct. 3rd.—4 P.M.: Mr. Gill-Carey: Foreign Bodies in the Food and Air Passages.

ST. PAUL'S HOSPITAL, Endell-street, W.C.
WEDNESDAY, Oct. 1st.—4.30 P.M., Dr. Nathan Mutch: Urinary Antiseptics.

Births, Marriages, and Deaths

BIRTHS.

GILLBARD.—On Sept. 14th, at Sherfield, Hants, the wife of Dr. Windham Gillbard, of a daughter.
LEWIS.—On Sept. 18th, at West End-lane, N.W., the wife of Dr. H. E. Lewis, of a son.

MARRIAGES.

ABERCROMBY—GLOVER.—On Sept. 17th, 1930, Roy William, son of Mr. and Mrs. William Abercromby, of Grassendale, Liverpool, to Barbara M. L. Glover, M.B., B.S. Lond., only daughter of Dr. and Mrs. Lewis G. Glover, of Hampstead, London.
LODGE—LANKESTER.—On Sept. 20th, at Clarendon Park Congregational Church, Leicester, Ralph Lodge, M.B., F.R.C.S. Edin., to Kathleen Mary Lankester, M.D., B.S. Lond.
SCARFF—SOMERVILLE.—On Sept. 16th, at St. Saviour's Church, W., Gordon Russell Scarff, F.R.C.S.E., to Janet Layton, younger daughter of the late F. G. Somerville, Singapore, and Mrs. Somerville, Maida Vale, W.

DEATHS.

HOWSE.—On Sept. 19th, at a London nursing home, after an operation, Major-General Sir Neville Howse, V.C., K.C.B., K.C.M.G., F.R.C.S., aged 67.
MACKENNA.—On Sept. 21st, 1930, at 76, Rodney-street, Liverpool, Dr. Robert William MacKenna, dearly loved husband of Harriet MacKenna. Interred at Allerton Cemetery, Liverpool, after service at the Cathedral.
MINNS.—On Sept. 16th, at Dorking, Allan Glaisyer Minns, M.R.C.S., L.R.C.P., late of Thetford, Norfolk, in his 72nd year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

MODERN VIEWS ON RHEUMATISM IN CHILDHOOD.*

BY E. C. WARNER, M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE CHILDREN'S DEPARTMENT, MILLER GENERAL HOSPITAL, GREENWICH; MEDICAL REGISTRAR, GUY'S HOSPITAL.

THE prevalence of rheumatism in childhood is brought home to us when we realise that of the 5,000,000 children in attendance at the elementary schools, about 250,000 suffer from this disease. Of these, at least 40,000 are known to have rheumatic heart disease, and about 25,000 persons die each year from its ravages, the majority in early youth. These are lives that we can ill-afford to spare; and even then we have not mentioned the large numbers of young people who spend years of chronic invalidism preceding the early death of the majority.

Ætiology.

It is not surprising therefore that a considerable amount of attention has been given to the factors underlying this disease during the last few years; there have been special reports of the results of the labours of committees set up in this country by the Ministry of Health, the Medical Research Council, and the British Medical Association; and from New York there have been the reports of the New York Tuberculosis and Health Association. From these, and from the work of many different physicians, among whom the most prominent have been F. J. Poynton, C. F. Coombs, R. H. Miller, G. F. Still, and L. Findlay, we are beginning to get an accurate insight into some of the causes underlying rheumatic disease in children. It is essentially a disease of a temperate climate. Thus in the northern hemisphere it is common in Great Britain, Scandinavia, Germany, France, Canada, and the U.S.A.; in the southern hemisphere it is common in South Africa and Australia. In the extreme north it is much less frequent, and it is found that the Eskimos are rarely affected; also as we near the tropics the incidence falls. D. Seegal showed that in the Southern States of America the incidence is only one-eighth to one-tenth of that found in the Northern States. The occurrence of the disease is much commoner in the winter and early spring months than it is in the summer months. It is especially prevalent in November, December, January, and February, and twice the number of attacks start in these months as compared with May, June, July, and August. In agricultural districts a smaller percentage of children is affected than in large towns.

DAMP.

Another climatic cause that has been investigated is dampness. Generally speaking, it is agreed that excessive dampness does predispose to rheumatism. A large number of rheumatic children live in the neighbourhood of rivers and water-courses, and so, for instance, the Wandle valley deserves censure in this respect. But this factor cannot be of extreme importance. The incidence was very low in the troops in Flanders during the war, although here terribly wet conditions prevailed for long periods. And surely if it had much effect the country labourer's child, who may have to walk long distances to school in very inclement weather, should be more, and not less, liable than his city cousin? In fact, it has often been noticed that years with a low rainfall cause more cases than very wet years; it seems as if the infecting agent is able to propagate more freely in the rainless years, and so cause more havoc amongst the child population.

HEREDITY.

Among the more immediate causes, most observers agree that where there is a family history of juvenile rheumatism many more cases occur. Thus is a recent investigation it was found that there was a family history of rheumatism in 58 per cent. of rheumatic children attending here or at Guy's Hospital, compared with 23·5 per cent. in non-rheumatic children. Dr. J. A. Glover in his recent Milroy lectures interpreted this as evidence in favour of direct infection from one member of a family to another. He has done great service in drawing attention to this possibility, and showed how any severe form of overcrowding in young adults, as in barracks, causes an outbreak of the disease. But in spite of this factor of infectivity, probably there is an inherited tendency as well, for we find that there was a much greater incidence of juvenile rheumatism among the grandparents of rheumatic children than among those of non-rheumatic children.

POVERTY.

No one disputes the fact that rheumatism is essentially a disease of the poor. As contrasted with the figures from the out-patients' department of this hospital, where every seventh child between the ages of 3 and 12 attends for rheumatic disease in one form or other, cases are rarely seen in the private practice of children's physicians. Thus Still says that amongst his private patients only 1 child in every 140 is brought to him on account of rheumatic disease. At Eton College the medical officer, Dr. W. H. Attlee, stated in a recent letter that he has only had one case of rheumatic disease amongst the boys during the past 19 years, and yet the elementary school-children of Eton show just as many cases as elsewhere in the country. We may well ask ourselves, What are the factors so closely associated with poverty which make rheumatism so very prevalent in the lower and so rare in the upper classes? Evidently climate cannot be the determining cause, and as we have already seen, it is not of much direct consequence. We can consider this subject on the same lines that many other diseases have been tackled in the past. For the disease to flourish, there must be a susceptible population, "the soil," and frequently in addition an infecting agent, "the seed." Without a suitable soil no seed can flourish. It seems that if we are to get to the bottom of this disease we should concentrate on the factors associated with poverty first, and then find out, if possible, what is the nature of the infecting agent. It is a striking fact that if we take poor children away from their environment and put them into relatively good social conditions they do not tend to develop rheumatism. This in itself shows that heredity is not of great importance. We find that children in the guardians' homes rarely develop rheumatic disease de novo. Thus in four such homes studied in the M.R.C. report, an incidence of only 1 per cent. was found, as contrasted with a general incidence in poor children of 5 to 6 per cent. And even then quite a number of the rheumatic children in these homes had had the disease before admission, and had a relapse after admission. This low infectivity-rate cannot be due to the absence of the virus, for this must have been present in the children who had had attacks before admission and who relapsed subsequently. The general supervision of these children must be of value, for usually they are under the supervision of trained foster-mothers, in well-built and well-ventilated cottage homes. But a factor that has not received the attention that it deserves seems to be the question of diet. No child can have an adequate resistance to disease if he is not properly fed. Probably the plain but good fare provided in these institutions is of immense value in raising the resistance of the children.

* An address delivered at the Miller Hospital before the West Kent Medico-Chirurgical Society.

VITAMIN DEFICIENCY.

In the first two years of life everyone recognises that the most prevalent poverty disease associated with poor feeding is rickets. We now know that this is due to absence of the vitamins found in animal fats. Lack of the fat-soluble vitamin D factor causes the bony changes of rickets itself, and the lack of the associated fat-soluble A factor causes lack of resistance to infection. This has been clearly shown by Prof. E. Mellanby both in human beings and in well-controlled experiments on animals. This lack of the vitamins D and A explains the common association of rickets with infective disorders of all kinds, such as bronchitis, broncho-pneumonia, diarrhœa, and vomiting.

At the age of 2 or thereabouts rickets practically ceases to show itself owing to the slower rate of growth of the child. But we should not expect a dietetic deficiency of this sort to cease to have *any* ill-effect. It is from the age of 2 upwards that rheumatic disease becomes a serious problem in poor children. Yet there is no disease which is recognised to take the place of rickets at the age of 2 years. I do not think it has been realised that rheumatic disease may well be a successor to rickets. You may well ask if there is any evidence for this; I think there certainly is. In the first place, anyone who has studied the diet of poor children realises that they receive very little in the way of animal fats. Milk, eggs, butter, meat, and cheese are all much too expensive for the poor mother to provide. She has to find cheap and bulky food to satisfy the appetite of the growing child, and so she concentrates on bread and other starchy foods (which are in themselves believed to be contributory to the development of rickets in infancy). On inquiry, one frequently finds that one or two pennyworth of milk a day has to serve a large family of poor people, adults and children; and margarine always has to serve for butter in the diet. I think it is evident that the animal fats are largely missing from the diet of poor children long after the age of 2. A second point is that this parallel between rheumatic disease and rickets at the different ages may help to explain why both are so very much more prevalent in the winter and early spring months. A point to which I would like to draw your attention is recent work on calcium metabolism in the poor. In the absence of adequate vitamin D, calcium is deficient in the body, as in rickets. When we study the calcium metabolism of rheumatic children, we find that the blood and cerebro-spinal fluid (and probably therefore other body fluids as well) are deficient in calcium.

Howland and Kramer found higher values in children than in adults, and this would still further accentuate the low values met with in children suffering from rheumatism and chorea. The reason that I mention the values in the C.S.F. is, that in the first place the values here represent the value of the active ionic calcium of the blood, and also, of course, the C.S.F. is the medium bathing the nerve cells. Corresponding to this low value in C.S.F. calcium, we find an increased electrical excitability of the nerve cells and fibres which I am sure is contributory to the choreic state, just as it is to tetany in infants. I hope I may have convinced you that it is well worth studying the diet of rheumatic children, as the absence of the fat-soluble vitamins may well help to explain the state of debility of the rheumatic child which may precede the signs of infection by many months or even years. This is a problem that no one has yet tackled seriously, and which we are just starting to investigate in this district with the help of the Medical Research Council.

THE INFECTING AGENT.

Reverting to our old analogy, do we know anything about "the seed"? Most observers agree that during the acute stages of rheumatism and chorea there is an infection. This must be the explanation of the little nodules scattered throughout the body, and so evident at post-mortem as the vegetations in the cardiac valves. But no one is as yet certain of the nature of the infecting agent. The most popular theory is that of Poynton and Paine that we are dealing with an infection with a diplococcus, the *Diplococcus rheumaticus*. I will not weary you with the evidence for and against this but it is by no means certain that this *is* the infecting agent. So far the *Diplococcus rheumaticus* has not fulfilled even one of Koch's four postulates.

Whatever the infecting organism may be, if we could find the paths of entrance into the body, can we block these, and in this way prevent infection? For a long time it has been assumed that the path of entrance is largely through the tonsils. It has often been pointed out that an attack of tonsillitis immediately precedes an attack of rheumatism in about 10 per cent. of cases, and this has led in many cases to the routine removal of tonsils in the hope of preventing this. It is well that we should carefully analyse the evidence, for should this be so, we have a wonderful prophylactic measure at our command. In the first place, we can only accept the statistics on children. Thus we cannot accept the often-quoted figures of Starling, of Mackie, or Lambert, as applying to children, as most of their cases were adults.

SORE-THROAT AND TONSILLITIS.

It is quite true that rheumatic children very commonly have a history of one or more sore-throats. Thus recent figures show that 48 to 58 per cent. of rheumatic children give this history. But in a control group of non-rheumatic children it was found that 58 per cent. of them also give a history of tonsillitis; in a very careful research carried out in New York it was found by Wilson, Lingg, and Croxford that there is a history of sore-throats in just as many children after their tonsils have been removed as when they have not been operated on!

Apart from this, are the tonsils of rheumatic children more "septic" than those of non-rheumatic children? The definition of a "septic tonsil" varies widely with different observers; certainly a tonsil is not necessarily septic because it is large—yet this is the apparent assumption made in the report of the Medical Research Council. Frequently a hypertrophied organ is a method of response to increased work, as when after nephrectomy the solitary kidney enlarges to take on the work previously performed by both of them. A definition of a "septic tonsil" should include a consideration of the degree of redness, superficial scarring, the presence of large red granulations projecting from the surface, the redness of the anterior pillars of the fauces, and the amount of debris in the crypts. Adopting all these criteria, a recent series of figures showed very septic tonsils in 6 per cent. of rheumatic children and 5 per cent. of non-rheumatic children; and septic tonsils in 45 per cent. of rheumatic children as compared with 48 per cent. of non-rheumatic children. So there is again no significant difference in the two groups. Similarly, a study of the size of the tonsillar group of lymph glands at the angles of the jaw showed equal enlargement in the rheumatic and non-rheumatic groups.

We can say, therefore, that although there is a large proportion of septic tonsils among rheumatic children, it is not higher than among non-rheumatic children of the same social standing.

Diagnosis.

There is rarely any doubt about the diagnosis of a case of acute rheumatism in a child, with its swollen, hot, tender joints and its general constitutional disturbances. Much more difficulty arises in cases of subacute rheumatism.

PAINS.

We usually class as cases of subacute rheumatism those children with flitting pains which may go from joint to joint, and yet never give rise to effusion, and also those cases in which the pains perhaps never

ctually occur *in* the joints, but are prevalent in the nuscles and tendons around the joints, and are opularly known as growing-pains. A state of lebility may exist for some months or years before he actual onset of rheumatism, and may predispose o it by lowering the vitality of the child. It may e a difficult matter to distinguish the various little ches and pains due to this debilitated condition rom the pains of true rheumatism. We cannot lways rely on the presence of heart murmurs to elp us in this matter. In these debilitated children xtracardiac, or so-called functional heart murmurs, re frequent, and may have to be distinguished from he murmurs of organic heart disease. I am sure it s wrong to regard all growing-pains as being rheuatic; and there are a few points which help us to istinguish those of true subacute rheumatism from hose of simple debility. First, the time of occurence of the pains is of importance. True rheumatic ains occur at any time of the day or night, and are specially noticeable at night, for the parents will ften complain that the child will "lie awake and ry with them." The debility pains are especially net with after exercise, and so a child may "stop nd want to be carried," but when he is taken off is feet the pains go. Secondly, usually the pains of ue rheumatism are severe, and may make the child ry; whereas the pains of debility are rarely more nan an "aching" or "tired" feeling. The third oint is that if we get the history carefully we almost lways find that true rheumatic pains involve the rms as well as the legs, whereas the pains of debility re usually confined to the legs. If we are still in oubt, we may be helped by the results of treatment. f the pains are simply due to debility, they will, as mphasised by Cameron and Osman, subside or be onsiderably ameliorated by giving large doses of lucose, whereas when they are of rheumatic origin his is not sufficient, although, of course, they will ield to salicylates.

CHOREA.

A fully developed case of chorea is easily diagnosed, ut sometimes an early or a mild case may be very ifficult to differentiate from the habit-spasms of a ervous or overwrought child. This is made more ifficult by the fact that children with chorea are apable of inhibiting the characteristic movements f this condition when they are brought for medical xamination. Here the history may be of considerble value; a child who is truly choreic has a history f "tripping over" or "falling about" to an abnormal xtent, and still more important, the finer movements f coördination are lost in simple movements, such s drinking from a cup; a child who suddenly starts o spill his tea at each meal is usually suffering from horea. It is equally important to observe these hildren performing natural movements when they o not think they are being observed; thus it is of reat value to see these children dress and undress hemselves for medical examination, for at such times he movements become much more evident.

CARDIAC SYMPTOMS.

The real importance of rheumatism and chorea om the point of view of prognosis and treatment as to whether the heart is affected. It is well that e should remember that if there is evidence of ffection of the pericardium, or the myocardium, or he endocardium, it is certain that all three parts are ffected to some extent; in other words, we are ealing with a pancarditis. When the pericardium chiefly affected, we get the signs and symptoms of dry pericarditis or of effusion, but on the whole his is becoming a relatively rare event compared to s frequency 30 and 40 years ago. Much more ommonly the myocardium is affected. The muscle iffers from both parenchymatous and interstitial hanges; there is, on the one hand, acute parenchyatous degeneration of the muscle, and, on the other, flammation of the interstitial tissue with the production of typical Aschoff's nodes. In this case we find on examination that the apex-beat is displaced outside the nipple line; and on percussion of the left border of the heart it is found to be outside its normal position. Associated with this dilatation there may be two types of murmur. The commonest is a short, soft apical systolic murmur, frequently localised to the actual apex, or just inside it; the other type is a reduplicated second sound at the apex, which may even develop into a short soft mid-diastolic murmur. As C. G. Kemp has recently shown, both these may disappear completely, and it is probable that both of them are of myocardial rather than of endocardial origin.

As contrasted with these soft murmurs, murmurs due to disease of the mitral valve, especially when they become advanced, usually give rise to harsh conducted murmurs, which may be heard well out in the axilla or over the sternum itself. These much more rarely disappear, but it is amazing that some which one would have thought could not be anything else than permanent, may gradually become less marked and even disappear completely with adequate treatment.

SUBCUTANEOUS NODULES.

The presence of large rheumatic nodules over the subcutaneous areas is happily rare nowadays, for they are almost invariably associated with very severe carditis. Any case that presents these nodules has large numbers of them actually in the wall of the heart itself, and this means severe myocardial and endocardial damage. Thus in a series of 33 cases which Poynton collected, 12 were fatal, 15 had severe heart damage, 4 had slight cardiac involvement, and only 2 were free from carditis.

Another nodule, on which Vincent Coates and Carey Coombs have laid stress, is the so-called subminiary nodule. These are said to be "pocket editions" of the more familiar large nodules, and to have the same significance. They are said to occur in rheumatic children often many months before there is any other sign of rheumatism, and to be present in 78 per cent. of rheumatic children, and never in non-rheumatic children. They are especially prominent in the flexor tendon sheaths, along the ulnar borders of the forearm, and over the vertebral spines, as little millet seed granules. They should therefore be of extreme value in the early diagnosis of rheumatic disease; but unfortunately they are not as conclusive as we are led to believe. After many months of practice, Dr. N. Gray-Hill and I recently went round the children's wards at Queen Mary's Hospital at Carshalton. We could certainly feel these granules in a large number of the children with tuberculous bone disease, although they were usually present in greater numbers in the rheumatic children. So we cannot rely on them as furnishing definite evidence of rheumatic trouble in children.

Treatment.

To be really successful with rheumatic disease we must get our cases in as early a stage as possible. As time goes on the general public is getting more and more educated in simple matters of general health, and thus parents are realising that many of the little "growing pains" of childhood may be of immense importance in pointing to the possibility of rheumatism, and so of an affection of the heart.

PRE-RHEUMATIC STATE.

Prevention is always better than cure, and it is well that we should be able to recognise the pre-rheumatic state of debility which so lowers the resistance of the child that he falls a ready victim to an acute attack of rheumatism or of chorea a few months later. I am sure that Prof. C. W. Vining is right when he remarks that if we take frankly rheumatic children and inquire into their past history, we usually find that for some months preceding the acute outbreak they have not been fit children. Common symptoms in these early months are pallor, undue fatigue on exertion, persistent headache not

associated with eyestrain, unexplained sweating, loss of weight, and signs of mental exhaustion such as night terrors, acquired enuresis, stammering, habit-spasms, irritability, and the exhibition of bouts of temper.

If we see the children in this stage, and particularly if there is a family history of juvenile rheumatism, we may prevent much trouble later on by getting the children really fit. This is where, in poor districts such as this, the Invalid Children's Aid Association is doing such valuable work, for this association will send such a child for convalescent treatment in more congenial surroundings for four or six weeks, and so may prevent lifelong mischief. Once such a child comes to look fit and well, with rosy cheeks, plenty of energy without getting overtired, and is putting on weight rapidly, there is very little danger of the supervention of rheumatism.

THE ACTIVE STAGE.

Unfortunately we do not always see the children at this stage, and may only be called to see them when they are already in the clutches of the infection. Then the general measures to be adopted are very much those we adopt in cases of tuberculosis—rest and quiet, plenty of good food, sunlight and fresh air in the acute stages, and the re-education of the heart when the active stage has passed. The problem we are faced with is how best to accomplish this. Undoubtedly the ideal thing is to send the child into a special institution in the country. The London County Council has such an institution at Carshalton, to which some 400 extra beds for rheumatic children are being added this year. The end-results of the treatment at Carshalton amply justify the expenditure involved. Although the cases sent to Carshalton were initially more severe cases than those treated at home, yet the relapses in the first three years are only half the number met with in cases which have not had prolonged institutional treatment. But the accommodation is such that over 70 per cent. of cases have to be treated in their own homes, under the care of the general practitioner. The ideal is to insist on absolute rest during the acute stages, although we all know how very difficult this is. In the one- or two-roomed homes, with the mother at work all day, and other children playing in the same room as the sick child, it becomes almost impossible. But assuming that our conditions are reasonably good, when are we to allow the rheumatic children to start a little extra activity; when, for example, should an extra pillow be allowed, and how soon may the child start to feed himself? Findlay has pointed out that if the heart is not involved in the first two attacks, it never is in subsequent attacks; so if we have seen the child through two attacks without carditis, we need not be so rigid in our measures in the third and subsequent attacks.

CARDIAC INVOLVEMENT.

When the heart has been involved the very minimum of complete rest is four weeks after active disease has subsided. How are we to know that the heart disease is quiescent? There are certain points that do help us in this matter. First, the temperature should be rigidly normal. A temperature which at night often goes up to 99·5° F. or over in a child who is lying absolutely quiet in bed is suspicious of active infection. Again, a constantly rapid pulse-rate usually means that the attack has not subsided. It is true that sometimes for months after all other signs of activity have disappeared the pulse remains rapid; in these cases it appears as if the normal vagal control of the heart has been lessened by the disease, and when the child is allowed up the pulse-rate falls, instead of rising; but on the whole these cases are rare. Another sign which I have found of value is the presence of sinus arrhythmia. Most healthy children show a rhythmical rise in pulse-rate with inspiration and a fall during expiration. My experience coincides with that of Dr. Martin Raven, that when sinus arrhythmia reappears usually active carditis has subsided. The other point I would like to stress is the character of the heart sounds and murmurs. During active carditis there is an accentuation of the first sound at the apex and of the pulmonary second sound at the base, which disappears when the disease subsides. Changing murmurs, particularly at the apex, mean that the heart is altering for better or for worse. First the short soft mid-diastolic murmur should disappear, then the apical systolic murmur becomes softer still and less marked, and finally *it* disappears. When the cardiac sounds have reached a constant state and the heart is keeping the same size as judged by the position of the apex-beat and of the left border of the heart, then usually the disease is quiescent; but these can only be appreciated by repeated examination.

SPECIFIC TREATMENT.

Nothing has superseded the administration of sodium salicylate for acute and subacute rheumatism. When large doses of sodium salicylate, combined with equal quantities of sodium bicarbonate are given regularly to a rheumatic child, the pyrexia and the pain and swelling have almost entirely gone in two or three days. Recently we have been trying the effects of sodium salicylate by intramuscular injection, and the results do show that this is of advantage in getting an even more rapid response. Usually the temperature is normal in 24 hours, and the pains and swellings have gone. The dose we have been using is gr. 1 for each year of the child's age, dissolved in 1 c.cm. of water, and given once a day for four days only. It is a great misfortune that the salicylates are not of equal value in controlling rheumatic cardiac disease. Everyone agrees that the heart is not benefited at all by salicylate therapy, and in my opinion it has a considerable disadvantage in that, once the acute pains have gone, the antipyretic effect may mask a little constant pyrexia which would show us that the disease is still active and so further rest in bed is necessary. In fact, there is no specific drug which controls the cardiac infection; but I certainly have seen cases with persistent tachycardia (which, of course, throws extra strain on the heart) benefited by digitalis.

For chorea, on the whole salicylates do not help to control the violent muscular movements, although some people have recorded benefit with aspirin. Arsenic is not of much value except occasionally in very large doses, and the risk of producing arsenical neuritis is such that I do not think this is justifiable. On the whole, large doses of various hypnotic drugs are undoubtedly beneficial. Thus chloretone and luminal are both good if pushed. But to get any real benefit the patient has to be rendered almost comatose, and so renders necessary constant skilled attention which cannot be obtained except in hospital. Recently Poynton and Schlesinger have reported good results with nirvanol, a hypnotic and sedative drug closely allied in its constitution to luminal. Usually in three or four weeks, if a sufficient dose is given so as to produce a temperature of 99°–104°, drowsiness and a rash, the chorea subsides on withdrawing the drug. This, again, can only be used in hospital, and really dangerous toxic symptoms are occasionally encountered, such as jaundice and nephritis.

In view of the known sedative effects of calcium salts on nervous and muscular tissues, and the considerable deficiency of calcium met with in chorea, I have recently been using intramuscular calcium chloride and parathormone. This latter drug is the active principle of the parathyroid glands, and injection of it raises the active inorganic calcium of the blood and cerebro-spinal fluid. About 90 per cent. of cases are undoubtedly benefited by it, and in the first 20 cases the average duration of the chorea was only four and a half weeks after starting treatment. I have had complete success with cases of chorea which have been going on continuously for 9 and for 24 months. These long-continued cases frequently show severe

ıental changes, and the improvement in the mental ɔndition has been most gratifying. The para-ıormone is given twice daily in doses of ♏ iv for child of 4 years, ♏ v at 7 years, and ♏ vi at) years. In these doses I have never had any toxic ffect, and even if an overdose is given the vomiting ɔ caused subsides immediately if the next dose is mitted. The only disadvantage is the price of the rug. A bottle of 5 c.cm. costs 16s., but the undoubted enefit is such that I think this is well justified in any ıt the very poorest cases.

TONSILLECTOMY.

A therapeutic measure often done as a routine to ısten recovery and to prevent relapses is to remove ıe tonsils. We have already seen that although ɔparently septic tonsils *are* frequent in rheumatic ıildren, they are not more frequent than in non-eumatic children of the same social class. It is ell that we should see whether this routine tonsillec-my *is* of advantage. Practically everyone who has udied this problem, and has had a group of non-nsillectomised children as a control, agrees that utine tonsillectomy is of no value. With regard to currences after tonsillectomy, the results are set t in the following Table :—

Percentage of Recurrences of Rheumatism in Children.

	(1) after tonsillectomy.	(2) not tonsillectomised.
Ingermann and Wilson ..	76	80
Hunt and Osman	53	42

d in the very carefully controlled groups of Wilson, ngg, and Croxford the conclusion reached was that e number of attacks is rather greater in the operated oup than in the non-operated group. Findlay, cfarlane, and Stevenson, working in Glasgow, ached the conclusion that there may be slight nefit in cases of rheumatism in preventing attacks arthritis and heart disease, but the evidence is only ghtly in favour of the tonsillectomised children as mpared with the non-tonsillectomised. Actually in orea, however, the number of attacks is more than ubled by a previous tonsillectomy, and tonsillec-my does not lessen the incidence of carditis. It is ite unknown why tonsillectomy should cause a eumatic child to develop chorea so much more en, but everyone who has worked on this subject s come to the same conclusion. So far, then, nsillectomy after the first attack of chorea or eumatism does not diminish the frequency of further acks or of heart disease, and actually in chorea it contra-indicated. While accepting this, it has been gued that if only tonsillectomy had been performed ore the first attack it might have prevented the set of rheumatism. Recently Dr. J. M. H. Campbell d I went through all our records here and at Guy's spital, and found that this is not true either. king all the children between the ages of 3 and 12 ending the children's out-patient departments, it s found that 15·3 per cent. of children who had l tonsillectomy on an average two years before umatism set in developed the disease, and 15·6 per t. of children who had never had tonsillectomy l likewise. Also the percentage who developed ditis was the same in the two groups.

think we may fairly sum up the problem of sillectomy by saying that it has no influence on initial onset or of recurrences, or of heart disease ; ually in choreic children it is contra-indicated ause it considerably increases the frequency of attacks. This does not mean to indicate that sillectomy is never justifiable in rheumatic ldren. If the tonsils are causing a condition of eral ill-health then they should be removed, in er to improve the general resistance ; but routine sillectomy is on the whole injurious and certainly beneficial. It appears as if the hypertrophied sils of rheumatic children may actually help in ing the resistance of the patient, as has long been ocated by Digby and by Canfield. The amount of hypertrophy of the lymphoid follicles in the naso-pharynx that one sees after tonsillectomy is often remarkable, as if the remnants are doing their best to take on the function of the removed tonsils. I have often been struck with the way the tonsils of children sent to Carshalton shrink in size during the stay there, as if under the better conditions prevail ing there the need for them is decreased. I do feel that if instead of enucleating the tonsils we were to treat tonsillitis in more serious fashion we should be doing much to lessen its sequelæ. Close and Osman have shown that the body metabolism does not return to normal until more than three weeks after an attack of tonsillitis, and during this time sequelæ such as nephritis and rheumatism may occur. If we were to treat tonsillitis with as much caution as we do scarlet fever we should see very much less of its sequelæ.

Conclusion.

This survey of the present position may not sound very cheerful, for with 250,000 rheumatic children to deal with in England and Wales we find we have no specific treatment apart from general hygienic measures. But the position is improving with the better conditions prevailing among the poorer classes. The death-rate per 1,000,000 from rheumatic fever in England and Wales has fallen from 87 in 1890 to 36 in 1927 ; and Sir Thomas Horder has pointed out that the severe cases with pericarditis, hyperpyrexia, and cerebral symptoms are much rarer than they were 30 or 40 years ago. If only we can gain more knowledge of the means of keeping up the resistance of the poor child, I feel sure we shall be well on the way to prevent rheumatism, and the great avenue remaining to be explored is the diet of the rheumatic child. But it is the general practitioner who sees these children in their pre-rheumatic state of debility, or in the early days of the disease itself, and our chief hope for the future must rest on his skill in recognising the true state of affairs, of dealing with them as promptly as possible, of referring severe or difficult cases for institutional treatment, and it is for him to keep observation on the children when they return and so minimise the risk of recurrence.

SWISS MEDICAL YEAR BOOK.

WE have received a copy for 1930 of this attractive calendar, which blossomed out last year into a handsome cloth-bound quarto volume. All the characters to which we then called attention have been retained, the year book has been brought scrupulously up to date, and additional care has been taken to make the information it contains easy of access. The book is ambitious in combining the scope of a medical directory and a medical annual, for the first 90 pages are given up to biographies and clinical summaries. Two great living Swiss clinicians, César Roux and Hermann Sahli, have their life-work set out in detail, and there is a delayed obituary notice of Carl Garrè. In the clinical survey Prof. F. de Quervain writes on the position of surgery, Prof. Paul Ernst of Heidelberg on waves in medical thought, Dr. A. Rollier on an international industrial clinic for poor persons suffering from surgical tuberculosis, and Prof. O. Veraguth on physical therapy. The year book is published by Benno Schwabe and Co. in Basle at 11 Swiss francs.

THE DUTCH PESSARY.

To the Editor of THE LANCET.

SIR,—The suggestion made in your admirable annotation on birth control (THE LANCET, July 19th, p. 147) that some British clinics may be using too small a size of occlusive pessary* is challenged in a subsequent letter from Dr. Norman Haire. Neither

*In this country we mostly prefer the coiled spring of the Ramses to the watch spring of the Mensinga, but the principle of fitting is the same.

the letter nor the annotation draw attention to the real danger of the smaller sizes—namely, that the patient may insert the ring between the anterior fornix of the vaginal vault and the symphysis pubis. The pessary must be large enough to make this impossible, except, perhaps, in the case of intelligent patients with long fingers who can be trusted to discover for themselves whether or no the cervix is covered. Otherwise the penis will reach the cervix between the pessary and the posterior wall of the vagina. Pessaries that are too large lie too nearly in the axis of the vagina (or, "too obliquely," as Dr. Haire would say). The danger in that case is that the penis may pass to the cervix between the pessary and the anterior wall of the vagina. Between these two misfits there is found one size, and usually not more than one size, that fits the patient, and is more or less fool-proof. In my experience this size is rarely less than 70 mm., and not very commonly more than 75 mm.

I am, Sir, yours faithfully,

J. ROSSLYN EARP.

Denver, Colorado, U.S.A., Sept. 5th, 1930.

*** The statistical evidence presented to the Zürich Congress was, as we noted last week (p. 650), unambiguous in its preference for the larger pessaries. —ED. L.

Appointments

DOHERTY, D., L.R.C.P., L.R.C.S. Edin., L.R.F.P.S. Glasg. has been appointed Temporary Assistant Medical Officer of Health, Donegal.

HUTTON-ATTENBOROUGH, E. A., M.B., B.S. Lond., Medical Referee under the Workmen's Compensation Act for County Court Circuit, No. 20.

LEWIS IVOR, M.D., M.S. Lond., Medical Superintendent, City Hospital, Plymouth.

Dewsbury Infirmary: CHAMBERLAIN, DIGBY, F.R.C.S. Eng., and MOIR, P. J., *M.C.*, F.R.C.S. Eng., Honorary Visiting Surgeons.

Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.: HATRICK, J. C., M.B., B.S., Senior Resident Medical Officer; NIXON, W. C. W., F.R.C.S. Eng., Assistant Resident Medical Officer; O'LEARY, MARY, L.R.C.P. Lond., M.R.C.S., D.P.H., District Resident Medical Officer.

Vacancies

For further information refer to the advertisement columns.

Alderley Edge, Ancoats Hospital Convalescent Home, Great Warford.—Hon. Visiting Physician. £50.

Alton, Hants, Lord Mayor Treloar Cripples' Hospital and College. 3rd Asst. Res. M.O.

Aylesbury, Royal Buckinghamshire County Hospital.—Hon. Consulting Surgeon to Throat, Nose, and Ear Dept.

Bath, Royal United Hospital.—H.S. At rate of £200.

Belgrave Hospital for Women, 1, Clapham-road, S.W.—H.S. and Two H.P.'s. Each at rate of £100.

Belgrave Hospital Infant Welfare Centre, 212, Camberwell New-road, S.E.—M.O. 1½ gns. per session.

Birmingham and Midland Eye Hospital, Church-street.—H.S. £110.

Blackburn Royal Infirmary.—4th H.S. £150.

Bootle General Hospital.—Hon. Ophth. Surgeon.

Burnley, Victoria Hospital.—H.P. At rate of £150.

Cambridge, Addenbrooke's Hospital.—H.S. Also Res. Anæsthetist and Emergency Officer. Each at rate of £130.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road.—Two Hon. Assts. for Out-patient Department.

Chesterfield and North Derbyshire Royal Hospital.—H.S. At rate of £100–£175.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—H.P. At rate of £100.

Colchester, Essex County Hospital.—Asst. H.S. and Reg. £120.

Connaught Hospital, Orford-road, E.—Res. H.S. At rate of £100.

Croydon General Hospital.—H.S. £125.

Eastbourne, Princess Alice Memorial Hospital.—H.S. At rate of £150.

East Ham Memorial Hospital, Shrewsbury-road, E.—H.P. At rate of £150.

Edinburgh, Dept. of Health for Scotland.—Regional M.O. in connexion with National Health Insurance Med. Service. £1000.

Edinburgh Royal Infirmary.—Radiologist, &c. £1500.

Evelina Hospital for Children, Southwark, S.E.—H.S. At rate of £120.

Exeter, Royal Devon and Exeter Hospital.—H.S. to Special Depts. At rate of £150.

Frimley Sanatorium.—Jun. H.P. At rate of £100.

Gloucester County and City Mental Hospitals.—Jun. Asst. M.O. £350.

Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—Second H.S. At rate of £120.

Great Yarmouth General Hospital.—Jun. H.S. At rate of £140.

Grimsby and District Hospital.—Res. M.O. £200.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—Hon. Dental S.

Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W.—Asst. P. Also Res. H.S.

Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—H.P. £50 for six months.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S. and H.P. Each at rate of £100.

Ipswich, East Suffolk and Ipswich Hospital.—Cas. O. £150.

Lancaster County Mental Hospital.—Asst. M.O. £350.

L.C.C.—Eighth Asst. M.O. for Mental Hospital Service. £44

Liphook, Hants, King George's Sanatorium for Sailors.—Asst. M.O. At rate of £200.

Liverpool, Alder Hey Children's Hospital.—Res. Asst. M.O. £20

Liverpool, Mill-road Infirmary.—Res. Asst. M.O. £200.

Liverpool Royal Babies' Hospital, Woolton.—Res. M.O. At rate of £90.

Liverpool, Smithdown-road Institution.—Res. Asst. M.O. £200

Liverpool, St. Paul's Eye Hospital, Old Hall-street.—H.S. At rate of £120.

Liverpool, Walton Hospital.—Res. Asst. M.O. £200.

Macclesfield General Infirmary.—H.S. At rate of £180.

Maidstone, Kent County Ophthalmic and Aural Hospital.—Hon. Ophth. S.

Manchester Babies' Hospital, Burnage-lane, Levenshulme.—Jun. Res. M.O. At rate of £50.

Manchester, Monsall Hospital for Infectious Diseases.—Jun. M.O. £350.

Manchester, Withington Hospital, &c.—Asst. M.O. £350.

Merthyr General Hospital.—Res. H. S. At rate of £150.

Middlesex Hospital, W.—Aural Surgeon. Dental Surgeon. Assistant Radiologist. £150.

Ministry of Health.—Deputy Regional M.O. in connexion with National Health Insurance Medical Service. £800.

Monmouthshire C.C.—Asst. M.O. £500.

Newcastle-upon-Tyne, City Hospital for Infectious Diseases.—Res. Med. Asst. £350.

Newcastle-upon-Tyne, General Hospital.—Sen. H.P. £300.

Newcastle-upon-Tyne, Hospital for Sick Children.—Hon. Opht Surgeon.

Oldham Royal Infirmary.—Two H.S.'s. Each at rate £175.

Paddington Green Children's Hospital, W.—H.P. and H. Each £150.

Plymouth, South Devon and East Cornwall Hospital.—H.S. rate of £100.

Pontypridd Women's Welfare Centre.—Woman Doctor for Bir Control Clinic. 1½ gns. per session.

Prince of Wales's General Hospital, Tottenham, N.—Sen. H.P and H.S.'s. All at rate of £120. Also Jun. H.P.'s a H.S.'s. All at rate of £90.

Radium Institute, Riding House-street, W.—Clin. Asst. At r of £300.

Reading, Royal Berkshire Hospital.—Cas. O. At rate of £150.

Richmond, Surrey, &c., Joint Isolation Hospital Committ Hospital, Mogden.—Res. M.O. £350.

Rochdale Infirmary and Dispensary.—Sen. H.S. £250.

Rowley Regis Urban D.C.—Temp. Half-time Asst. M.O.H., £300.

Royal Free Hospital, Gray's Inn-road, W.C.—Res. Cas. O. £1

Salford Royal Hospital.—H.S. At rate of £125.

Shanghai Municipal Council, P.H. Dept.—2nd Asst. Commissioner of P.H. 650 Tls. per mensem.

Sheffield Royal Hospital.—H.S. Also Ophth. H.S. Each at r of £80.

Southampton Children's Hospital and Dispensary for Women. Res. M.O. At rate of £100.

Southampton, Royal South Hants and Southampton Hospital. Asst. H.S. At rate of £180.

South London Hospital for Women, South Side, Clapham Comm S.W.—H.P. and H.S. Each at rate of £80.

St. John's Hospital, Lewisham.—H.P., H.S., and Cas. O. Ea at rate of £100.

St. Pancras Metropolitan Borough.—Asst. M.O. £500.

St. Mary's Hospital for Women and Children, Plaistow, E.—R and Asst. Res. M.O.'s. At rate of £175 and £120 respective

Sunderland, Durham County and Sunderland Eye Infirmary. Two Ophth. Surgeons. Each £350.

Swansea Hospital.—H.S. £150.

Wakefield, West Riding Mental Hospital.—Jun. Asst. M.O. £4

CASSELL & CO., LTD., LA BELLE SAUVAGE, LONDON, E.C.4.

PUBLISHED SEPTEMBER 3rd.

THE CLINICAL INTERPRETATION OF AIDS TO DIAGNOSIS

Volume One.

Companion Volumes to the "Modern Technique in Treatment" Series.

IN the volumes dealing with Treatment, and in the subsequent articles still being issued under that heading, there are references to the need which the practitioner may have of particular advice from the laboratory worker and the radiologist. This need grows more regular as scientific medicine progresses, so that clear advice as to the meaning and value of the expert reports has now become necessary.

The first volume of THE CLINICAL INTERPRETATION OF AIDS TO DIAGNOSIS providing this assistance is uniform with the "Modern Technique in Treatment" Series. It comprises 388 demy octavo pages, including 45 illustrations, fully indexed under titles of articles and authors. Published at 10s. 6d. net (postage: inland 6d., abroad 9d., extra).

FOR CONTENTS OF THE VOLUME SEE FOLLOWING PAGE.

CONTENTS OF VOLUME I.

THE WIDAL OR AGGLUTINATION REACTION IN THE DIAGNOSIS OF INFECTIONS DUE TO THE ENTERIC GROUP OF MICRO-ORGANISMS. By A. B. Rosher, M.R.C.S., D.P.H.

REPORTS ON SWABS FROM THE THROAT AND NASAL PASSAGES. 1. CASES SUSPECTED OF DIPHTHERIA. By J. E. McCartney, M D., Ch.B , D.Sc.

REPORTS ON SWABS FROM THE THROAT AND NASAL PASSAGES. 2 CASES NOT SUSPECTED OF DIPHTHERIA. By J. E. McCartney, M.D , Ch.B., D.Sc.

THE INTERPRETATION OF REPORTS ON SPUTUM. 1 COLLECTION OF MATERIAL: PHYSICAL AND CHEMICAL CHARACTERISTICS. By S. Roodhouse Gloyne. M.D. Leeds, D.P.H. Lond

THE INTERPRETATION OF REPORTS ON SPUTUM 2. CELLULAR AND BACTERIAL CONTENT: UNUSUAL SUBSTANCES. By S Roodhouse Gloyne, M.D Leeds, D P H Lond.

THE INTERPRETATION OF REPORTS ON THE CEREBRO SPINAL FLUID. 1 THE PRACTITIONER'S RESULTS. By J. G. Greenfield, M.D Edin., F.R.C P. Lond.

THE INTERPRETATION OF REPORTS ON THE CEREBRO-SPINAL FLUID. 2. THE PATHOLOGIST'S RESULTS. By J. G. Greenfield, M.D Edin., F.R.C P Lond.

THE SIGNIFICANCE OF HEARING TESTS. By Harold Barwell, F.R.C.S. Eng.

THE INTERPRETATION OF THE BLOOD COUNT. 1 THE RED CELLS. By S. C. Dyke, D.M. Oxf., M R.C.P. Lond.

THE INTERPRETATION OF THE BLOOD COUNT. 2. THE WHITE CELLS. By S. C. Dyke, D.M. Oxf., M.R.C.P. Lond.

THE ARNETH OR POLYNUCLEAR COUNT. By W. E. Cooke, M.D. Liverp , M.R.C.P Lond

TESTS OF RENAL EFFICIENCY 1. GENERAL CONSIDERATIONS: UREA-CONCENTRATION TEST. By G. A. Harrison, M.D.

TESTS OF RENAL EFFICIENCY 2 BLOOD ANALYSIS: DYE TESTS. By G. A Harrison, M D.

THE DETERMINATION OF THE PRESENCE AND SIGNIFICANCE OF REDUCING SUBSTANCES IN URINE. 1. THE PRACTITIONER'S RESULTS. By E. C. Dodds, M.D , Ph.D., M R.C.P. Lond.

THE DETERMINATION OF THE PRESENCE AND SIGNIFICANCE OF REDUCING SUBSTANCES IN URINE. 2. THE BIOCHEMIST'S RESULTS. By E. C. Dodds, M D , Ph.D , M.R C P. Lond.

THE CHEMICAL EXAMINATION OF FÆCES. By J. H. Ryffel, B Sc. Lond , B.Chir. Camb.

THE INTERPRETATION OF BREAST HISTOLOGY. By Sir G. Lenthal Cheatle K C.B , F R.C.S. Eng.

THE INTERPRETATION OF THE WASSERMANN REACTION IN CHILDREN. By David Nabarro, M.D., F R C.P Lond.

THE INTERPRETION OF BLOOD-SUGAR ESTIMATIONS. By George Graham, M D. Camb., F R.C.P. Lond.

THE SIGNIFICANCE OF OCULAR TESTS. 1. MONOCULAR TESTS By R. Affleck Greeves, F.R C S Eng.

THE SIGNIFICANCE OF OCULAR TESTS. 2. BINOCULAR TESTS. By R. Affleck Greeves, F.R C S Eng.

THE CLINICAL SIGNIFICANCE OF THE BLOOD-UREA CONTENT. By O. L. V. de Wesselow, B.M. Oxf., F.R C P. Lond.

THE ELECTROCARDIOGRAM. 1. NORMAL RECORDS. By Crighton Bramwell, M.A. Camb., M.D. Manch., M.R C.P. Lond.

THE ELECTROCARDIOGRAM. 2. ABNORMAL RECORDS. By Crighton Bramwell, M A. Camb , M.D. Manch., M R.C.P. Lond.

REPORTS ON MATERIAL CURETTED FROM THE UTERUS. By Thomas G Stevens, M D Lond., F.R.C.S Eng.

ALBUMINURIA. By J. C Spence, M D Durh , M.R C.P. Lond.

THE SIGNIFICANCE OF ORGANISMS IN THE URINE 1. PRELIMINARY TESTS FOR INFECTION. By Lionel E. H. Whitby, M.D Camb , M R.C.P Lond.

THE SIGNIFICANCE OF ORGANISMS IN THE URINE. 2. IDENTIFICATION OF THE ORGANISM. By Lionel E. H. Whitby, M D. Camb., M.R C.P. Lond.

THE INTERPRETATION OF BASAL METABOLISM TESTS. By Leslie Cole. M.D. Camb., M.R.C.P. Lond.

THE CLINICAL SIGNIFICANCE OF THE BLOOD-PLATELETS. 1. By W. Cramer, Ph.D , D Sc , M.R.C S., and R. G Bannerman, M.D., Ch.B.

THE CLINICAL SIGNIFICANCE OF THE BLOOD-PLATELETS. 2. By W. Cramer, Ph.D , D Sc M R C S., and R. G. Bannerman, M.D., Ch.B.

PYELOGRAPHY. By J. B. Macalpine, F.R.C S. Eng.

PLEURAL FLUIDS By L S. T. Burrell, M.D., F R.C.P.

When is Diathermy of Value in Your Practice?

YOUR decision to use diathermy in the treatment of any condi-on will, of course, be based on cognized medical authority. lany doctors have become interest-l as a result of observing the any references to diathermy in irrent medical literature, and no ubt intend to investigate for emselves when opportunity esents. But a busy practice fords little of the time required searching the files of the medical rary, and it is put off indefinitely.

A preliminary survey of the ticles on diathermy, published ring the past year or so, is ailable to you in the form of a -page booklet entitled "Indications for Diathermy." In this booklet you will find over 250 abstracts and extracts from articles by international authorities, including references to more than a hundred conditions in the treatment of which the use of diathermy is discussed.

If you number yourself among the doctors who have not adopted diathermy in practice, and desire to investigate this form of therapy in view of reaching your own conclusion as to its value in your practice, you will find this booklet a convenient reference. A copy will be sent on request.

Ideal Shadowless Lamp

For Illumination in Operating Theatres

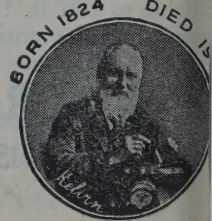
A MOST efficient illuminant for surgeons. Provides an intense, shadowless, cool, and diffused light.

Can be tilted as required by a touch.

Ceiling suspension and wall bracket patterns.

Low first cost; low maintenance; easy to instal.

The shadowless illumination is produced by scientifically designed reflecting surfaces, no lenses being employed.



The late Lord Kelvin. Chairman 1900-1907.

MICRO-CURIE THERAPY

In his article, "*About the application of Radioactive substances in cases of internal diseases, a few skin diseases and thyreotoxides,*" **Prof. Dr. F. Gudzent,** of the Berlin University, writes:—

". . . . . a period of research, stretching over 25 years has led to a pretty reliable judgment. Cures have now been reported, even if sometimes partially and cursory, of the following diseases:

1. *Sub-acute and chronic rheumatism of the joints.*
2. *Gout and gouty diathesis.*
3. *Muscular rheumatism.*
4. *Neuralgia and neuritis (sciatica).*
5. *Chronic abscesses and inflammations.*
6. *Chronic inflammatory diseases of sexual organs.*
7. *Some chronic skin diseases (psoriasis, eczema, seborrhœa, lichens, erythematous lupus, scleroderma, nævy, dermatitis, burns caused by Röntgen rays).*
8. *Symptoms of senile decay.*
9. *Myocardism, heart neurosis, arterio-sclerosis.*
10. *Secondary and pernicious anæmia.*"

RADIUMCHEMA compresses are made in the State factory in St. Joachimsthal under the control of the Ministry of Health of the Czecho-Slovakian Republic.

RADIUMCHEMA compresses are tested and sealed by the Radiological Institute in Prague and the Curie Institute in Paris.

RADIUMCHEMA compresses are *ABSOLUTELY HARMLESS.*

RADIUMCHEMA compresses can be obtained at £7; the Radiumchema booklet free on application.

OLIVITA

OLIVE OIL WITH VITAMIN D

Olivita consists of the finest Virgin Olive Oil to which has been added that proportion of Irradiated Ergosterol which gives it a Vitamin D content equivalent to that of Cod Liver Oil.
Having investigated the conditions under which Boots Olive Oil is produced in Spain, the finest grade of Olive Oil available is guaranteed to be the first pressings from the Olives.
Olivita will be found very palatable and can be recommended without hesitation to regular users of Olive Oil.
The wide range of usefulness of Olive Oil is well known, and members of the medical profession will readily appreciate the further advantages conferred on this product by the incorporation of the sunshine Vitamin D.
Recent researches have indicated that substances containing Vitamin D should form part of the diet of all children during the period while the permanent teeth are being calcified. Cod Liver Oil is now often given to babies as a regular part of their diet as a good source of Vitamin D and Olivita provides a palatable alternative.
Its keeping properties have been thoroughly tested and the uniformity of its vitamin content is controlled by Biological tests.

For Mother and Child

It is generally admitted that, if the physique of the next generation is to be improved, special care must be directed towards the proper feeding of the expectant and nursing mother, and of the child from birth to school age.

According to the teachings of modern dietetics the daily administration of an adequate supply of vitamins is of paramount importance.

In prescribing Radiostoleum for the mother and child—whether in normal health or ailing—the physician is prescribing an accurately-standardised scientific preparation possessing one hundred times the Vitamin D activity and fully twenty times the Vitamin A activity of high-grade cod-liver oil.

Radiostoleum, therefore, is a product of remarkable and unvarying potency; it possesses the advantage, also, accruing from its relatively small dosage.

Alasil

Analgesic Antipyretic Sedative

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"ALASIL" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill-conditions of the gastric tract.

"ALASIL" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time.

Analgesic, Antipyretic, and Sedative, "ALASIL" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

184, Queen's Gate, London, S.W.7

M.236

Successful Treatment of Hyperchlorhydria and Associated Conditions

"Alocol" (Colloidal Hydroxide of Aluminium) has proved remarkably successful in the treatment of hyperchlorhydria, gastric ulcer, fermentative dyspepsias with gastro-intestinal flatulence, acid eructation and other symptoms common to gastric disease.

The advantages of "Alocol" are that it actually removes from the system the causative acid radicle (Cl) instead of merely neutralising it, and so permitting reabsorption, accumulation and consequent recurrence of the symptoms of the disease.

Furthermore, "Alocol" neither hinders proteolysis nor causes destruction of any food element or factor. "Alocol" has a distinct healing and sedative effect; it promptly allays irritation by absorbing acid and other irritants.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

ALOCOL

Colloidal Hydroxide of Aluminium

PRACTICAL PROPHYLAXIS
AGAINST

Common Colds and Catarrh

Save valuable time in prevention and treatment by using

MULFORD-SEROBACTERINS

(Antigen and Antibody Combinations)

Some immediate protection afforded.
Highest Antigenic Value.
Cause less local and systemic reaction because method of preparation reduces toxicity.
Larger doses may be given and at shorter intervals.

CATARRH "COLDS" SEROBACTERIN, MIXED

(Sensitized Bacterial Vaccine)

This p roduct differs from ordinary vaccines because it is "sensitized," that is, the bacteria have previously been treated with homologous immune serum, from which have been absorbed quantities of their respective antibodies. No serum is present in the preparation, however, the bacteria having been washed completely free of it. A degree of immediate passive resistance is conferred by injection of the serobacterin, by reason of the setting free of some of the antibodies. This degree of resistance persists until active immunity has been established. The formula includes :— Staphylococcus (aureus and albus), Streptococcus, B. Friedlander, Pneumococcus (Types I, II, and III), M. Catarrhalis.

Vita-Weat contains every part of the wheat berry

When a diet regime is prescribed it is usual to include Vita-Weat, the British whole-wheat crispbread, in place of soft whole-meal or white bread.

Vita-Weat is an article of diet combining the nutritive and health-giving properties of the best wholemeal bread with the palatability of the white loaf, at the same time ensuring an easily digested product with a high Vitamin, Caloric and Protein content.

It is an all-British crispbread, guaranteed to be made from 100 per cent. stone-ground whole-wheat grown within the Empire. It is of distinctive texture, inviting mastication and insalivation; it has a delicious "crunchiness" and a pleasing ripe-corn flavour; and it contains every part of the wheat berry, nothing whatever being removed in the process of manufacture.

Not the least of the many benefits to be obtained from a regular diet of Vita-Weat is that of intestinal correction and the prevention of many of the intestinal and gastro-intestinal ailments due to constipation.

When forming a suitable proportion of the daily diet, Vita-Weat acts as a stimulant to normal peristalsis, whilst not exerting an undue irritative effect on the intestinal mucous membrane.

Measuring Progress by the Therapeutic Yardstick

ANCIENT medicine set great store by "specifics." Paracelsus had his "Specificum Purgans." Cophon relied on mirobolanum or rhubarb in relieving constipation. Suppositories of honey and oxgall had their day in the fifteenth century.

Medicine has since made notable advances toward rationalism. In this day of therapeutic progress Agarol Brand Compound holds the foremost place. An exceptionally fine emulsion of mineral oil and agar-agar with phenolphthalein, it is not merely a laxative, but a remedial measure in the efficient treatment of constipation.

By introducing unabsorbable moisture, Agarol Brand Compound keeps the intestinal contents soft and makes their passage easy and painless. By *gentle stimulation* of peristalsis, it makes the result certain and aids in re-establishing normal bowel function.

One tablespoonful at bedtime —is the adult dose

Final decision on the true worth of Agarol Brand Compound rests with the physician. We will gladly send a liberal quantity with literature, for trial.

Alternative Methods in Prophylaxis and Treatment of

CORYZA

DETOXICATED ANTI-CORYZA VACCINE. This Vaccine has been used with great success for several years. Its outstanding feature is the absence of reaction, which makes it especially useful for hyper-sensitive patients.

ORDINARY ANTI-CORYZA VACCINE. Some Practitioners consider that a slight reaction has definite therapeutic value, and this type of Vaccine has been prepared to meet their requirements. It has the advantage of very low price.

ANTI-CORYZA VACCINE SPRAY (For local application to the nose and throat). For patients who object to Vaccine treatment by subcutaneous injection, and for children, this Local Immunity Product is particularly indicated. An additional convenience is that frequent attendances by the patient for injections are unnecessary.

Additional information regarding the above products will gladly be supplied to any Practitioner who writes to The Vaccine Department, Genatosan Ltd., Loughborough, Leicestershire.

Streptococcus Antitoxins

INVESTIGATIONS of the hæmolytic streptococci have led to the recognition of specific strains etiologically related to such infections as scarlet fever, erysipelas and puerperal fever, and to the production of specific antitoxins for use in these diseases.

ERYSIPELAS ANTITOXIN

A concentrated and refined serum obtained from the blood of horses immunized to the toxin and cultures of strains of streptococci believed to be specific to erysipelas. For the treatment of erysipelas the dose of this antitoxin is 10 c.c. repeated in 24 hours. Usually two doses are sufficient.

Supplied in bulbs of 10 c.c.

PUERPERAL SEPTICÆMIA ANTI-STREPTOCOCCUS SERUM

Obtained from the blood of horses immunized to the toxin and cultures of strains of streptococci isolated from cases of puerperal septicæmia, and indicated as either a prophylactic or therapeutic agent.

Supplied in bulbs of 10 c.c.

STREPTOCOCCUS ANTITOXIN (SCARLATINA)

A concentrated and refined serum obtained from the blood of horses immunized to the toxin and cultures of *Streptococcus hæmolyticus scarlatinæ*. Prepared and standardized under licence from the Scarlet Fever Committee by arrangement with the Drs. Dick.

Supplied in bulbs containing one therapeutic dose and in bulbs containing one prophylactic dose.

MEDULLA RUBRA

BONE-MARROW IN ANÆMIA FROM HÆMORRHAGE

W. Borchardt (*Deut. med. Woch.*, March 28th, 1930, p. 521) records the results of his experiments on young dogs in which anæmia had been artificially produced by the removal of about half their blood. In the first series some of the animals were fed with rib-marrow, others with marrow from the long bones. Control animals received a corresponding amount either of fat or of liver extract. The basal diet in each case contained a sufficiency of iron (5 mg. per cent.). Only the animals receiving the red rib-marrow showed a definite increase of weight, and their hæmoglobin formation was more rapid than that of the others. In the next series the experiment was repeated, but the iron content of the diet was reduced to 1·4 mg. per cent. The result was similar but more striking, the dogs receiving the rib-marrow regaining their hæmoglobin far more quickly than the others.

THIS extract from the "Epitome of Literature," published in the "BRITISH MEDICAL JOURNAL" dated May 3rd last, is important as representing, in 1930, a complete justification of the formula upon which

Roboleine

THE FOOD THAT BUILDS THE BODY

has been produced without variation during the past twenty-five years.

The success of ROBOLEINE is thus due to intelligent anticipation and to consistently maintaining the highest possible standard of manufacture.

Medical Practitioners are asked to satisfy themselves of the merits of ROBOLEINE, for which purpose testing samples will be gladly sent upon request.

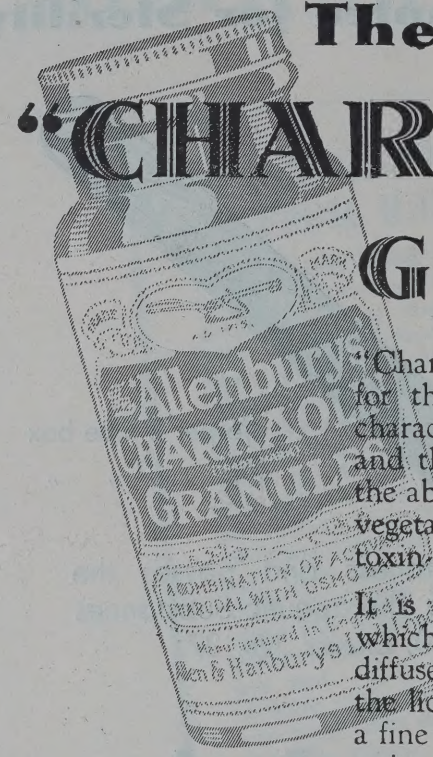
"CHARKAOLIN"

GRANULES

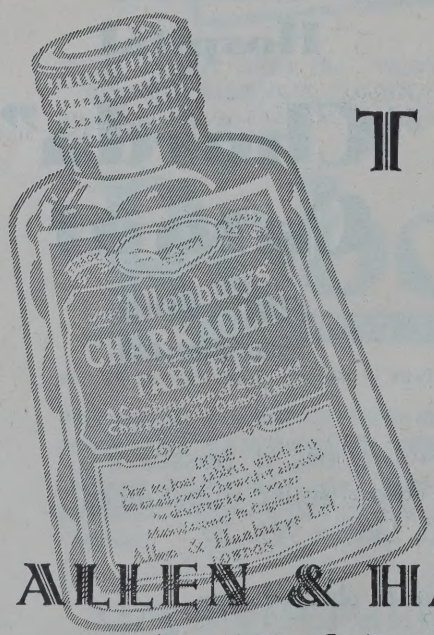


"Charkaolin" is a highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin-adsorbing qualities of "Osmo" Kaolin.

It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. "Charkaolin" is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

In bottles at 2/6 each.

TABLETS



The "Allenburys" "Charkaolin" Tablets provide a convenient alternative method of administering "Charkaolin." Particularly suitable when travelling. Tasteless and disintegrate readily.

In bottles:
40 tablets - 1/6
80 tablets - 2/6

THE PROPHYLAXIS of "Common Cold"

It is now recognised that Common Cold, Coryza, Rhinitis, and Bronchitis respond to vaccine administration in the majority of cases. Experience has shown that the most favourable results are obtained if the Vaccine Course be commenced some twenty days before the season when the patient is usually susceptible. The vaccine specified below is especially adapted for prophylactic purposes in persons subject to such attacks and also for the treatment of inflammatory conditions of the upper air passages, particularly when bronchitic symptoms are present.

EVANS' Common Cold Vaccine No. 3 (Prophylactic)

Micrococcus catarrhalis	200 mills.
Diplococcus pneumoniæ	200 „
Streptococci	200 „
Bac. Friedlander	100 „
Bac. Septus	100 „
Staphylococci (alb. & aur.)	200 „
Micrococcus tetragenus	100 „
Bacillus influenzæ	100 „

1200 mills. per c.c.

Supplied in 1 c.c. ampoules, rubber capped bottles, and boxes of graduated doses.

A brochure on Vaccine Therapy will be sent, post free, on application.

AN EARLY FORM OF THE MANUSCRIPT WRITING OF THE "ARABIANS." Some of the most prominent men who built up the Arabian Empire were not true Arabs, but Syrians, Greeks, Persians, Copts, Indians and Hispano-Arabians. They achieved a remarkable unanimity, however, in the Arabic language. The ancient learning of Arabia reached the Western world largely through the medium of Arabic translations. Roger Bacon recognised that these were more scholarly than many of the Greek and Latin versions and he counselled the study of Arabic as the best means of acquiring knowledge. But for these translations certain parts of Aristotle and Galen would have been lost to the world.

"ANZYPAN" TABLETS.

Exhaustive tests with "ANZYPAN" tablets, made by me in this Laboratory under conditions which approximate as nearly as possible to those in the body, affirm:-

(1) the presence of pepsin, trypsin, diastase, lipase and gall, the amounts of which were estimated;

(2) that these ferments and gall as presented in "ANZYPAN" tablets digest protein, fat and starch;

(3) that the pepsin in the outer coating is rapidly dissolved in an acid medium (dilute HCl. as found in the stomach);

(4) that the other ferments and gall are so protected in the construction of the tablet that they are unaffected by long immersion in an acid medium of physiological strength at body temperature;

(5) that the trypsin, diastase, lipase and gall are rapidly disintegrated in an alkaline medium approximating to the conditions in the small intestine.

ONLY BREAKAGE CAN DESTROY ITS HEALTH VALUE

Only by breakage can you destroy the value of "Vita" Glass as a permanent inlet for the ultra-violet rays.

One of the most interesting tests ever made in proof of this permanency is being carried out by the Building Research Station, and an interim report states: — "The behaviour of 'Vita' Glass in sunshine cannot be deduced from artificial solarisation without serious risk of error." "Vita" Glass exposed to artificial radiation regains its solarised level of transmission on subsequent exposure to natural daylight, after which continued exposure to sunlight causes no further change.

Those interested in "Vita" Glass for their own use or for use in buildings under their control are invited to write for full particulars to the "Vita" Glass Marketing Board, 11, Crown Glass Works, St. Helens, Lancashire.

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers and Builders.

"VITA" GLASS

health through your windows

DEAFNESS

Doctors prefer "ARDENTE" for self or patient because . . .

MEDICAL REPORTS.
Commended by all leading medical journals. —Mr. Dent will be happy to send full particulars and reprints on request.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported, as evidenced by the interest shown at the last B.M.A. Meeting.

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true to tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

FREE HOME TESTS ARRANGED FOR DOCTORS AND PATIENTS.

NATURAL APERIENT MINERAL WATER

RUBINAT LLORACH

(Hydragogue, Purgative and Cholagogue).

The official analysis shows in each litre about 1601·321 grains of *Anhydrous Salts*, of which are *Sulp. Soda* 1485·368 grains, and *Sulp. Magnesia* 50·301 grains.

Prescribed in cases of Gall-stones, Liver Disease, and threatened Appendicitis, Constipation associated with Gout, Hepatic Dyspepsia, Gastric Fever, and generally in Abdominal Obstruction.

Dose:—Wineglassful fasting; can be increased according to temperament. Effect is more rapid if followed by a cup of hot tea.

NO GASTRIC IRRITATION. NO ALTERATION IN DIET REQUIRED.

"A moderately powerful stimulant of the liver, and a powerful stimulant of the intestine."

SOLVING A FOOD PROBLEM

HOVIS

the most nourishing Bread

After all the discussions as to the relative values of white, wholemeal and various brown breads it is satisfactory to have conclusive evidence at last.

Following many experiments by various research workers it is shown that no bread contains so large a percentage of Vitamin B as Hovis, or is such an active agent for healthy growth when forming the basis of the diet.

As is now well known, even a partial deficiency in Vitamin B in the diet, if lasting for any length of time impairs health and with children prevents perfect development.

Hovis even in small quantities provides sufficient vitamin in a digestive form as no other bread does, and it is liked by all.

Richest in Vitamin B

Hovis Bread consists of White Flour with the wheat germ incorporated. It is this which gives it its special value, since the germ is the part richest in the Vitamin.

The "Brownness" of bread is not a measure of its vitamin content. Further, the goodness of Hovis is fully absorbed into the system because, unlike wholemeal bread which has a tendency to pass through the body without the nourishment being properly extracted, Hovis contains no bran and is digested naturally and easily, retaining all its richness.

The evidence is conclusive. For providing the maximum of nourishment economically no bread equals Hovis.

HŌVIS

Best Bakers Bake it

HOVIS LTD. LONDON & MACCLESFIELD

FLATULENCE AND ALIMENTARY FETOR

MANY conditions are associated with flatulence, some of which frequently give rise to embarrassment of distant organs.

Dyspepsia, catarrh and ulceration of the stomach and intestine, cancer, dysentery, and other diseases of the alimentary canal itself, neurasthenia, and diseases of the heart, liver and pancreas, to name only a few, may all be associated with flatulence and intestinal flatus.

Some of the diseases of the intestine, such as dysentery and cancer, are often also associated with horrible fetor of the evacuations.

The accumulation of flatus in the stomach and intestine is liable to embarrass the action of the heart and lungs, giving rise to dyspnœa, disordered action of the heart, faintness and even anginal attacks.

Both the flatulence and fetor are the result of abnormal fermentation and putrefaction of the contents of the alimentary canal; apart from treatment of the condition itself, it can be rationally controlled by the use of an efficient intestinal disinfectant. For this purpose, Kerol, the most potent germicide, being unabsorbed and non-toxic, is unsurpassed, and can be safely administered in sufficient amount to exert its germicidal action.

When the fermentation is located in the stomach, KEROL CAPSULES (Gastric) m. 3, should be administered: one or two may be given three or four times a day after meals.

When there is intestinal flatus and fetor, the keratin-coated KEROL CAPSULES m. 3, should be used, the dose being one to three after meal.

Intestinal **Disinfection**

Kerol Capsules

STANIFORM

TRADE BRAND MARK

Methyl Stannic Iodide

OINTMENT
Immediately stops the pain in all cases of burns, scalds, &c.

DUSTING POWDER
For application where a greasy substance is counter-indicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION
A panacea for Mosquito and other insect bites. Most effective for all purposes where Tr. Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical men:

"I continue to get every satisfaction from 'Staniform' in the case of carbuncles, boils, whitlows, and all kinds of infected wounds."

"In a case of acute eczema on leg, the skin was quite normal within one week after starting application of 'Staniform Ointment.'"

"Festering wound on left heel when first seen was about the size of a shilling with good deal of pus: Foot much swollen—dressed with 'Staniform Ointment' healed splendidly in four days."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of burns, wounds, and skin ailments.

STANIFORM is used in leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties: Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations inducing an immediate soothing effect with rapid healing.

STANIFORM LTD., CARNWATH ROAD, LONDON, S.W.6.

Bronamalt

The Ideal Tonic Nutrient.

"I gave BRONAMALT in a case in which digestion was very slow and imperfect. The result was excellent, nutrition improved, and, as one would have expected, the digestive process was hastened and was free from the previous concomitant symptoms of flatulency associated with palpitation. Constipation, which had been a most troublesome feature of the case, was quickly relieved. I have formed a very high opinion of its merits." 6314 r.—M.D.

"I have had occasion to prescribe BRONAMALT in several cases of late. I find it a useful tonic where the digestive powers are feeble, and it is very effective in the 'run-down condition' not uncommon to many people in the Spring and Autumn. It has the great merit of being both elegant and palatable and appears to be an effective method of administering Cinchona." 17623 m—M.D.

every nurse should know . . .

A NURSE owes it to her own professional pride and to the safety of her patient to know the facts about Lysol. When Lysol was first discovered a formula was worked out: a specification evolved for the manufacture of a perfect antiseptic and germicide. This is the formula: this the specification used to-day in the manufacture of Marshall's Lysol . . . Marshall's Lysol costs a few pence more than other brands, because every bottle sold is uniform in purity: because every precaution that science teaches is taken to maintain this high standard.

Other Lysols may contain inferior ingredients: impurities may make them caustic, irritant . . . But Marshall's Lysol used as directed is harmless to skin and tissue: death to disease. It is an essential part of every nurse's equipment. Never use Marshall's Lysol undiluted.

From all chemists, IN BOTTLES, 1/-, 1/9, 3/-, & 5/-.
The larger sizes are more economical to buy.
Sample sent upon request to members of the Medical and Nursing Professions.

MARSHALL'S *Lysol*

LYSOL LIMITED, RAYNES PARK, LONDON, S.W.20

THIS PREPARATION IS NOW OBTAINABLE IN 5-oz. BOTTLES.

"MIST. PEPSINÆ CO. c. BISMUTHO"

(HEWLETT'S).

COMPOSITION.—Pepsin, Bismuth, Sol, Opii Purif., Hydrocyanic Acid (B.P.), Tinct. Nux Vomica, &c.

An elegant preparation, miscible with water, invaluable in Gastric Catarrh, Pyrosis, Carcinoma, and all Forms of Atonic and Irritative Dyspepsia.

DOSE: Half to One Fluid Drachm Diluted.

Packed for Dispensing only in 5, 10, 22, 40, and 90-oz. Bottles. Price in England, 12/6 per lb.

This preparation also supplied "sine Opio," the price and dose remaining the same.

THE CARDIAC ARRHYTHMIAS

EXTRASYSTOLES, PAROXYSMAL TACHYCARDIA, AURICULAR FLUTTER AURICULAR FIBRILLATION are all substantially the same in functional pathology.

THE RESTORATION OF RHYTHM depends upon re-establishing the dominance of the normal pace-maker of the heart—the sinus impulse.

Anasarcin steadies and regulates the heart cycle, enabling the sinus impulse to gather strength and resume its pace-making function. The cardiograph has demonstrated the action of Anasarcin in restoring rhythm and tone to the disordered heart.

Let us send you literature giving evidence of its efficacy, and samples to demonstrate it for yourself.

THE ANASARCIN CHEMICAL CO., Winchester, Tennessee, U.S.A.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

PRESIDENT: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.
MEDICAL SUPERINTENDENT: DANIEL F. RAMBAUT, M.A., M.D.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, bio-chemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital, in detached grounds with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian Baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, &c. There is an operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for bio-chemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit and vegetables are supplied to the Hospital from the farm, gardens and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard court), croquet grounds, golf courses and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts such as carpentry, &c.

For terms and further particulars apply to the Medical Superintendent (TELEPHONE: No. 56 Northampton), who can be seen in London by appointment.

THE OLD MANOR SALISBURY

A Private Hospital for the Care and Treatment of those of both sexes suffering from MENTAL DISORDERS.

Extensive grounds. Detached Villas. Chapel. Garden and dairy produce from own farm. Terms very moderate.

CONVALESCENT HOME AT BOURNEMOUTH standing in 12 acres of ornamental grounds, with tennis courts, etc., which Patients or Boarders may visit, by arrangement for long or short periods.

Illustrated Brochure on application to the Medical Superintendent, The Old Manor, Salisbury. Telephone: 51.

The salary is £600 per annum, rising by yearly increments of £25 to a maximum of £750. There is also a yearly allowance of £10 for travelling expenses.

The person appointed will be required to contribute to the Superannuation Scheme of the Corporation.

Forms of application may be obtained from the undersigned and applications should be returned not later than Saturday, 27th September, 1930.

GEORGE GUEST, Acting Director of Education.

Education Offices, Deansgate, Manchester.

City of Birmingham.

SELLY OAK HOSPITAL.

CASUALTY OFFICER (MALE).

Applications are invited from fully qualified Medical Practitioners for the Whole-time appointment of Casualty Officer (Male) at the Selly Oak Hospital, Birmingham.

The present Hospital accommodation is 550 beds, divided into General Medical, General Surgical, Gynæcological, Obstetrical, and Children's Disease sections. There are completely equipped Pathological and Biochemical Laboratories and X Ray, Electrotherapeutic, Massage, Ultra-violet Ray, and Electrocardiographic Departments. Over 3000 operations are performed annually.

The appointment will be for a period of six months in the first instance, but may be extended at the end of that time for a further period of not exceeding six months.

The person appointed will be required to assist at operations, to administer anæsthetics, and to undertake casualty and such other duties as may be assigned to him by the Medical Superintendent.

The salary attached to the appointment is at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance). The Officer appointed will be required to account to the Council for all fees, allowances, and emoluments (other than the foregoing) received by him.

Further particulars of the appointment may be obtained from the Medical Superintendent, R. P. Stanley Kelman, Esq., M.B., F.R.C.S. (Eng. and Edin.), at the Selly Oak Hospital, to whom applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, should be forwarded not later than Wednesday, 24th September, 1930.

F. H. C. WILTSHIRE, Town Clerk.

The Council House, Birmingham, August, 1930.

Bristol General Hospital.

Notice is hereby given that a meeting of the Election Committee will be held at the Hospital at 1 o'clock P.M. on Wednesday, October 8th, 1930, for the purpose of electing an HONORARY DENTAL SURGEON. Applications, together with proof of qualification, to be forwarded to the undersigned on or before Monday, September 29th, 1930.

N.B.—An Honorary Assistant Dental Surgeon is a candidate for the appointment.

By order of the Committee,
September 10th, 1930. THOMAS W. GREGG, Secretary.

Southampton Children's Hospital and
DISPENSARY FOR WOMEN. (45 Beds.)

The Board of Management invite applications for the post of RESIDENT MEDICAL OFFICER (Lady). Appointment for six months. To commence duties on October 1st. Salary at the rate of £100 per annum, with board, residence, and laundry. Applications, stating age, and accompanied by copies of testimonials, to be sent to the undersigned, from whom further particulars may be obtained.

ELLA K. MATTHEWS, Secretary.

The King Edward VII. Welsh
NATIONAL MEMORIAL ASSOCIATION.

Applications are invited from duly registered Medical Practitioners for the post of ASSISTANT RESIDENT MEDICAL OFFICER at the GLAN ELY TUBERCULOSIS HOSPITAL, Fairwater, near Cardiff. Salary £250 per annum, plus maintenance; the appointment being limited to a period of twelve months.

Applications, stating age, qualifications and experience, together with copies of three recent testimonials, should reach the undersigned by September 24th, 1930.

D. A. POWELL, Principal Medical Officer.
Memorial Offices, Westgate-street, Cardiff.

Bury Infirmary, Lancashire.
(A General Hospital of 170 Beds.)

Applications are invited for the post of THIRD HOUSE SURGEON, who must have both Medical and Surgical qualifications, and have had some experience in the administration of Anæsthetics. The appointment is for six months, at a salary at the rate of £150 per annum, with board, residence, and laundry.

Applications, stating age, qualifications, and nationality, with copies of three recent testimonials, to be sent to the undersigned not later than the 24th September, endorsed "Third House Surgeon."

ALEX. W. MAITLAND, Honorary Secretary.

Northampton General Hospital.
(230 Beds.)

There will be vacancies on October 1st next for Two ASSISTANT HOUSE SURGEONS. British nationality. Salary £150 per annum, with board, residence, and laundry.

The successful candidates will be appointed for a period of six months, and will be eligible for re-election for a further period.

Candidates must be duly qualified and registered.

Applications, stating age, sex, qualifications, &c., with copies of testimonials, to reach the undersigned not later than first post on the 24th September, 1930.

15th September, 1930. H. ST. JOHN WOOD,
Secretary Superintendent.

National Radium Centre for
MANCHESTER.

The Committee wish to appoint a RADIUM REGISTRAR (Male) in connection with the above Centre. The appointment will be non-resident, and a minimum salary of £350 per annum will be given. Possibly the duties will be combined with others at the Manchester and District Radium Institute, and in that case the salary might be considerably augmented for a suitable applicant.

Applications should reach the Hon. Secretary, National Radium Centre for Manchester, The Radium Institute, Nelson-street, Manchester, not later than September 30th, 1930.

Gloucester County and City Mental
HOSPITALS.

JUNIOR ASSISTANT MEDICAL OFFICER (Male, single) wanted. Salary £350 per annum, with four annual increments of £25; such increases are conditioned by the obtaining of a Degree or Diploma in Psychological Medicine and will not be retrospective. Three months' study leave (D.P.M.) may be granted during the second year.

The appointment is subject to the provisions of the Asylums Officers' Superannuation Act, 1909, and for this purpose the emoluments, consisting of board, washing, and apartments, are valued at £104 per annum.

Applications, stating age and qualifications, together with copies of three recent testimonials, to reach the Medical Superintendent, County Mental Hospital, Gloucester.

Taunton and Somerset Hospital
(104 Beds), Taunton.

SENIOR HOUSE SURGEON required. Applicants must have held a Hospital Resident appointment for at least six months.

Salary at the rate of £150, with board, residence, and laundry. Three residents altogether.

Applications, with testimonials, to F. J. J. STACEY, Secretary.

Ancoats Hospital Convalescent Home,
Great Warford, Alderley Edge.

Applications are invited for the post of HONORARY VISITING PHYSICIAN to the above. Honorarium £50 per annum. Applications, stating age, qualifications, &c., to be in by 1st October next, accompanied by not more than three recent testimonials, and to be forwarded to the undersigned, from whom all particulars can be obtained.

By Order of the Board.
HERBERT J. DAFFORNE, General Superintendent and Secretary.

Northern Infirmary, Inverness.

Wanted immediately, THIRD RESIDENT MEDICAL OFFICER, fully qualified, registered, male, unmarried. Appointment will be for six months. Salary at the rate of £100 per annum, with board, residence, and laundry. Applications, stating age, medical school, qualifications, and experience, with copies of recent testimonials, to be sent to Mr. ROBT. GILBERT, Hon. Secretary, Inverness.

Walsall General Hospital.

The Committee invite applications from men for the post of HOUSE SURGEON. Salary £150 per annum.

Candidates, who must be registered under the Medical Acts, must produce three recent testimonials.

The appointment will be for six months.

The Hospital contains 100 beds, and is equipped in all Special Departments.

Applications, stating age, qualifications, and nationality, must be received by the undersigned immediately.

WALTER FRANCOMBE, Secretary.

NEW ZEALAND.

Christchurch Hospital Board.

The Board invites applications for a MEDICAL REGISTRAR. Salary £500 per annum, with board and lodgings. Applications should be forwarded to the Secretary, Hospital Board, Christchurch, New Zealand.

Shanghai Municipal Council.

PUBLIC HEALTH DEPARTMENT.

SECOND ASSISTANT COMMISSIONER OF PUBLIC HEALTH (HOSPITALS).

A Second Assistant Commissioner of Public Health (Hospitals) is required in the Public Health Department of the Shanghai Municipal Council.

Candidates, preferably unmarried, should not be more than thirty years of age, and must hold qualifications in Medicine and Surgery of University standard; a D.P.H., though not essential, is desirable. Candidates must have held Resident Hospital appointments, medical and surgical and practical experience of Isolation Hospital, V.D. and T.B. services is desirable.

Salary Tls. 650 per mensem, or Tls. 700 per mensem if holding a D.P.H., during three years' agreement.

The agreement is renewable, in the event of satisfactory services, at a triennial increase of Tls. 100 per mensem up to Tls. 1,000 or Tls. 1,050 per mensem if holding a D.P.H.

A tael at the present rate of exchange equals about 1s. 7d. Exchange is, however, subject to fluctuation.

A temporary bonus of Tls. 75 per mensem is issued at the present time to compensate for the increased cost of living and under certain limitations a guarantee of one-third of pay and bonus will be paid at the equivalent of 2s. 6d. to the Tael to offset the adverse fluctuations in the rate of exchange.

The Assistant Commissioner of Public Health (Hospitals), provided he holds the D.P.H., is eligible for the higher appointments of Deputy Commissioner of Public Health and Commissioner of Public Health, the present maximum pay for which is Tls. 1,350 and Tls. 2000 per mensem respectively.

First-class passage is given with half-pay during voyage.

Eight months' leave is given on full pay, with first-class passage, after every period of five years' service in Shanghai.

Free medical attendance is provided, and there is participation in the benefits of a Superannuation Fund.

Particulars of the appointment, and full details as to the benefits enjoyed by Municipal employees under their terms of service, may be obtained from the Council's agents.

Applications, in candidates' own handwriting, with full information as to their qualifications, experience, &c., accompanied by at least three recent testimonials, and endorsed "Second Assistant Commissioner (Hospitals)" on the cover, should be forwarded to Messrs. JOHN POOK & Co., Agents for the Municipal Council of Shanghai, 68, Fenchurch-street, London, E.C.3.

September, 1930.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(Founded 1880)

Tele. Address: Triform, Wesdo—London. **12, Stratford Place, Oxford Street, W.1.** Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the British Medical Association has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

MEMBERS OF THE BRITISH MEDICAL ASSOCIATION MAY TAKE ADVANTAGE OF A REDUCED SCALE OF CHARGES APPLICABLE TO THEM.

For the sake of reference the business undertaken by the BRITISH MEDICAL BUREAU is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the BRITISH MEDICAL BUREAU. Vendors may depend upon receiving introductions only to eligible and bona fide purchasers. All information is treated in strictest confidence.

Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the BRITISH MEDICAL BUREAU to ensure that only the most TRUSTWORTHY AND RELIABLE Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the BRITISH MEDICAL BUREAU. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The BRITISH MEDICAL BUREAU has its own staff of fully qualified Accountants wholly engaged on Medical work, i.e., Investigation of Practices for purchasers, Income Tax, Auditing books and accounts, etc.

SCHOLASTIC DEPARTMENT

Medical Men will find this Department of the BRITISH MEDICAL BUREAU of great assistance in the selection of Educational Establishments, Private Tutors, Governesses, etc. Prospectuses and advice gratis.

All correspondence and applications should be addressed to **A. V. STOREY, General Manager.**

NOTES ON THE
USES OF 'LUMINAL'
No. 2.—'Luminal' in Vomiting

'Luminal,' the specific in epilepsy, has also proved highly effective in the control of vomiting. An authority describes his experiences in this connexion, as follows:—

"In vomiting due to gastritis, food intoxication, high fever, uræmia or pregnancy, 'LUMINAL' SODIUM seldom failed. It is prescribed for adults as follows: 'Luminal' sodium, gr. 3 to 5, according to the constitution of the patient and the severity of the case, and gr. 30 of cocoa-butter, to form a suppository. If desired, gr. 1½ of 'Anæsthesin' can be added to the mixture, in order to ensure complete absence of irritation. Also additions of extract of belladonna, extract of opium, &c., can be advantageous in certain cases, for example, where pain or tenesmus are present. The effect of the suppository commences in 15 to 20 minutes. The patient becomes sleepy and apathetic (it is important that he should be placed in suitable surroundings), and the vomiting ceases. This method is especially valuable for patients with acute intestinal catarrh or alimentary intoxication, whose tissues are completely desiccated after prolonged vomiting, as it allows the absorption of water to take place when the alimentary canal has been quietened down. As soon as the patient begins to be sleepy, water may be administered by mouth, and 10 minutes later even animal charcoal, which usually promotes vomiting readily, may be retained in the stomach. The effect of the 'Luminal' suppository is generally prolonged, and it is seldom necessary to repeat the administration within 12 hours. In vomiting of pregnancy, a suppository is best given in the evening. It secures sound sleep, the action lasts throughout the night, and as a rule the morning vomiting is absent. Further, in intractable hyperemesis gravidarum, and also in violent retching following the administration of narcotics, 'Luminal' suppositories proved very successful."—(Blumenthal-Med. Klinik, 1929, No. 3.)

'Luminal,' brand of phenyl ethyl malonyl urea, and its soluble salt 'Luminal' Sodium, the original products of the Bayer Laboratories, are issued in tablet form in a variety of doses and packings and also as a powder.

To obtain results—insist upon the Original.

Valentine's Meat-Juice

For **Quieting** the **Irritable Stomach**, for **Aiding** the **Digestion** and for **Sustaining** and **Strengthening, Valentine's Meat-Juice** is **Extensively Employed** in the treatment of

Phthisis.

Dr. Saturnino Garcia Hurtado, *Physician Rubio Institute and Municipal Asylum, Madrid, Spain:* "In cases of Consumption, General Debility, etc., VALENTINE'S MEAT-JUICE is most beneficial. I have sometimes noticed that the hemorrhages which occur in hemorrhagic diseases are apt to cease after the administration of VALENTINE'S MEAT-JUICE, which indicates that it acts as a tonic on the nervous system, which is worthy of note."

Dr. Vires, *Adjunct Professor, University of Montpellier, France:* "I have used VALENTINE'S MEAT-JUICE with Tuberculosis Patients and with convalescents from Infectious Diseases, Typhoid Fever, Pneumonia, &c., and observed that my patients derived from its use very marked benefit which could be quickly noticed."

ANTIPHLOGISTINE

has been recognised as an appropriate adjuvant in Roentgeno-therapy. X-rays are considered to be the most useful single therapeutic agent in the hands of the dermatologist for the treatment of *Eczema* and other persistent *Skin Affections*, but they may prove disappointing when used to the exclusion of local adjuvants.

A satisfactory application wherever inflammation and congestion are present.

For thirty-six years it has served the Profession faithfully and well.

Antiphlogistine, by relieving itching and pain and, at the same time, softening and soothing the indurated tissues, is a valuable agent in skin diseases treated with X-rays.
